1. Introduction

The electrode systems generating a quadrupole electric field, having both static and variable components, allow to maintain the charged particles in a well defined region of space without physical solid contact with the wall of a container. This process is sometime called *levitation*. Usually, these kinds of devices are known as *quadrupole traps*. The operation of a quadrupole trap is based on the *strong focusing* principle (Wuerker et al., 1959) used most of all in optics and accelerator physics. Due to the impressive results as high-resolution spectroscopy, frequency standards or quantum computing, the research has been directed mainly to the ion trapping. Wolfgang Paul, who is credited with the invention of the quadrupole ion trap, shared the Nobel Prize in Physics in 1989 for this work. Although less known, an important amount of scientific work has been deployed to develop similar devices able to store micrometer sized particles, so-called *microparticles*. Depending on the size and nature of the charged microparticles to be stored, various types of quadrupole traps have been successfully used as a part of the experimental setups aimed to study different physical characteristics of the dust particles (Schlemmer et al., 2001), aerosols (Carleton et al., 1997; Davis, 1997), liquid droplets (Jakubczyk et al., 2001; Shaw et al., 2000) or microorganisms (Peng et al., 2004). In this paper the main outlines of a study regarding the effect of a low frequency acoustic wave on a microparticles cloud which levitates at normal temperature and atmospheric pressure within a quadrupole trap are presented. The acoustic wave generates a supplementary oscillating force field superimposed to the electric field produced by the quadrupole trap electrodes. The aim of this experimental approach is evaluating the possibility to manipulate the stored microparticles by using an acoustic wave. That means both controlling their position in space and performing a further selection of the stored microparticles. It is known that, as a function of the trap working parameters, only microparticles whose charge-to-mass ratio \( Q/M \) lies in a certain range can be stored. Such a selection is not always enough for some applications. In the case of a conventional quadrupole trap where electrical forces act, particle dynamic depends on its charge-to-mass ratio \( Q/M \). Because the action of the acoustic wave is purely mechanical, it is possible decoupling the mass \( M \) and the electric charge \( Q \), respectively, from equation of motion. An acoustic wave can be considered as a force field which acts remotely on the stored microparticles. There are two important parameters which characterize an acoustic wave, namely wave intensity and frequency. Both of them can be varied over a wide range so that the acoustic wave mechanical effect can be settled very precisely. The experiments have been focused on the acoustic...
frequency range around the frequency of the ac voltage applied to the trap electrodes, where resonance effects are expected. Comparisons between experimental results and numerical simulations are included.

2. Linear electrodynamic trap

To store the micrometer sized particles (microparticules), in air, at normal temperature and pressure, the electrodes system shown in Fig.1 has been used. The six electrodes consist of four identical rods (E1, E2, E3, E4), equidistantly spaced, and two end-cap disks (E5, E6). The rod electrodes E2 and E3 are connected to a high ac sinusoidal voltage \( V_{ac} = V_0 \cos 2\pi f_0 t \). The electrode E4 is connected to a dc voltage \( U_x \) while the electrode E1 is connected to the ground. The end-caps electrodes E5, E6 are connected to a dc voltage \( U_z \). Such an electrodes arrangement is known as a linear electrodynamic trap. A linear electrodynamic trap is characterized by a simple mechanical layout, confines a large number of microparticles and offers good optical access. For an ideal linear electrodynamic trap, near the longitudinal axis \( x, y \ll R \), assuming \( L_z \gg R \) and neglecting geometric losses, the electric potential may be expressed approximately as a quadrupolar form (Major et al., 2005; Pedregosa et al., 2010):

\[
\phi(x, y, t) = \frac{(x^2 - y^2)}{2R^2}(U_0 + V_0 \cos \Omega t)
\]

where \( R \) is the inner radius of the trap and \( \Omega = 2\pi f_0 \). The voltage \( U_z \) assures the axial stability of the stored particles while the electric field due to the voltage \( U_x \) balances the gravity force. In the particular case of the linear electrodynamic trap used in this work, the diameter of the rods and distance between two opposite rods are both 10 mm, therefore \( R=5 \) mm. The distance \( L_z \) between the end-cap disk electrodes can be varied between 30 mm and 70 mm. During the experiments, the distance \( L_z \) has been kept at 35 mm. The dc voltages \( U_z \) and \( U_x \) can be varied in the range 0-1000V, while the ac voltage \( V_{ac} \) is on the order of 1-4kV\(_{rms}\) at a frequency from 40 to 100 Hz. The usual values for the voltages applied to trap electrodes are summarized in Table 1. Microparticles cloud is confined in a narrow region along the longitudinal trap axis (see Fig.2 ). To avoid the perturbations produced by the air streams the whole trap is placed inside a transparent plastic box. The charged microparticles are stored inside the trap for hours in a quasi interaction free environment. More details on the linear electrodynamic traps mechanical layout can be found in (Gheorghe et al., 1998; Stoican et al., 2001). The motion of a charged particle in a quadrupole electric field is very well known e.g. (Major et al., 2005; March, 1997) and an extensive review are beyond the scope of this paper. Here will be summarized only the basic equations necessary to perform an appropriate numerical analysis of the effect of an acoustic field on the stored microparticles. Taking into account the expression (1) of the electric potential and the presence of a supplementary force due to the

Table 1. Summary of the electric voltages applied to the linear trap electrodes. The electrode E1 is connected to ground.

www.intechopen.com
acoustic field, equations of motion in the (x,y) plane for a charged particle of mass $M$ and charge $Q$, located near the linear trap axis, are:

$$M \frac{d^2 x}{dt^2} = -\frac{Q_x}{R^2} (U_0 + V_0 \cos \Omega t) - k \frac{dx}{dt} + F_{Ax}(t)$$

(2)

and

$$M \frac{d^2 y}{dt^2} = \frac{Q_y}{R^2} (U_0 + V_0 \cos \Omega t) - k \frac{dy}{dt} + F_{Ay}(t)$$

(3)

The terms $-k \frac{dx}{dt}$ and $-k \frac{dy}{dt}$, describe the drag force exerted on an object moving in a fluid. Assuming that the particles are spherical, according to Stokes’s law:

$$k = 6 \pi \eta (d/2)$$

(4)

where $d$ is the diameter of the charged particle while $\eta \approx 1.8 \times 10^{-5} \text{kgm}^{-1}\text{s}^{-1}$ is the air viscosity at normal pressure and temperature. The time-depended terms $F_{Ax}(t)$ and $F_{Ay}(t)$, stand for the force exerted by the acoustic wave on the stored particle. The $Ox$ is the vertical axis. The microparticles weight has been neglected. Making change of variable $\xi = \Omega t/2$ the equations (2) and (3) can be rewritten as:

$$\frac{d^2 x}{d\xi^2} + \delta \frac{dx}{d\xi} + (a_x + 2q_x \cos 2\xi)x - s_{Ax} = 0$$

(5)
and
\[ \frac{d^2y}{d\xi^2} + \delta \frac{dy}{d\xi} + (a_y + 2q_y \cos 2\xi)y - s_Ay = 0 \] (6)

The dimensionless parameters \(a_x, q_x\) and \(\delta\) are given by:
\[ a_x = -a_y = \frac{4QU_0}{M\Omega^2R^2} \] (7)
\[ q_x = -q_y = \frac{2QV_0}{M\Omega^2R^2} \] (8)
\[ \delta = \frac{6\pi \eta d}{M\Omega} \] (9)

The time dependent functions \(s_{Ax}(t)\) and \(s_{Ay}(t)\) are given by:
\[ s_{Ax}(t) = \frac{4F_{Ax}}{M\Omega^2} \] (10)
\[ s_{Ay}(t) = \frac{4F_{Ay}}{M\Omega^2} \] (11)

The pair \((a,q)\) defines the operating point of the electrodynamic trap and determines entirely the characteristics of the particle motion. In the absence of the terms due to the drag force \((-k\frac{dx}{dt}\) and \(-k\frac{dy}{dt}\)) and the acoustic wave \(F_{Ax}(t)\) and \(F_{Ay}(t)\), a differential equation of type (5) or (6) is called the Mathieu equation (McLachlan, 1947). It can be shown that solutions of a Mathieu equation describe a spatial bounded motion (stable solutions) only for certain regions of the \((a,q)\) plane called stability domains. This means that, a charged particle can remain indefinitely in the space between the trap electrodes. Additionally, the charged particle trajectory must not cross the electrodes surface implying the supplementary restrictions in its initial position and velocity. One could say that, within the stability domains, a potential
barrier arises preventing the stored charged particles to escape out of the trap. As an example, for the first stability domain, if \( a_x = 0 \), the stable solutions are obtained if \( 0 < q_x < 0.908 \). The first domain stability corresponds to the lowest voltages applied to the trap electrodes. Due to the air drag area of the first stability domain is enlarged so that, depending on the value of \( \delta \), the particle can remain inside the trap even if \( q_x > 0.908 \). Operation within the higher order stability domains is not practical because of very high voltage to be applied across the trap electrodes. As can be seen in (7) and (8) the operating point depends on the electrodynamic trap geometry, electrodes supply voltages characteristics and charge-to-mass ratio of the stored particle. Knowing the operating point of the trap, its dimensions and applied voltages, then charge-to-mass ratio of the stored particle can be estimated. If \( \delta = 0 \), \( F_{Ax,y} = 0 \), \( |a_x|, |a_y|, |q_x|, |q_y| \ll 1 \) (adiabatic approximation), the differential equations (5) and (6) have the solutions (Major et al., 2005):

\[
\begin{align*}
 x(t) &= x_0 \cos(\omega_x t + \varphi_x)(1 + \frac{q_x}{2} \cos \Omega t) \\
y(t) &= y_0 \cos(\omega_y t + \varphi_y)(1 + \frac{q_y}{2} \cos \Omega t)
\end{align*}
\]

where

\[
\omega_x = \frac{\Omega}{2} \sqrt{\frac{q_x^2}{2} + a_x}
\]

and

\[
\omega_y = \frac{\Omega}{2} \sqrt{\frac{q_y^2}{2} + a_y}
\]

Under these conditions the motion of a charged particle confined in a quadrupole trap can be decomposed in a harmonic oscillation at frequencies \( \omega_i/2\pi \) called "secular motion" and a harmonic oscillation at the frequency \( f_0 = \Omega/2\pi \) of ac voltage called "micromotion". As a consequence the motional spectrum of the stored particle contains components \( \omega_i/2\pi \) and \( f_0 \pm \omega_i/2\pi \) \((i = x, y)\). For arbitrary values of the parameters \( a_{x,y}, q_{x,y} \) and \( \delta \), equations (5) or (6) can be numerically solved.

3. Experimental setup

The experimental setup is based on the method described in (Schlemmer et al., 2001) used for a linear trap. The scheme of the experiment is shown in Fig.3. The output beam of a low power laser module (650 nm, 5 mW) is directed along the longitudinal axis (Oz axis) of the linear trap. A hole drilled through one of the end-cap electrode (E6) allows the laser beam illuminating the axial region of the trap where the stored particles density is maximal and the electric potential is well approximated by the relation (1). A photodetector PD placed outside of the trap and oriented normal to the laser beam receives a fraction of the radiation scattered by the stored particles and converts it into an electrical voltage \( U_{ph} \) proportional to the incident radiation intensity. To prevent electrical perturbations due to the existing ac high voltage applied to the electrodes trap, the photodetector is encapsulated in a cylindrical shielding box. The effect of the background light is removed by means of an appropriate electronic circuit. The acoustic excitation of the stored microparticles is achieved by a loudspeaker placed next to the trap. The loudspeaker generates a monochromatic acoustic wave with frequency \( f_A \). In this way both electrical field created by the trap electrodes and the force due to the acoustic wave act simultaneously on the stored microparticles. The motion of the stored particles...
modulates the intensity of the scattered radiation. Therefore the photodetector output voltage $U_{ph}$ contains the same harmonic components. By analysing changes in the structure of the frequency domain spectrum of the voltage $U_{ph}$, the effect of the acoustic wave on the stored particles can be evaluated. For this purpose a measurement chain whose block diagram is shown in Fig. 4 has been implemented. A digital low frequency spectrum analyser is used to determine the harmonic components of the voltage $U_{ph}$. The loudspeaker is supplied by the low frequency power amplifier A1 which is driven by the low frequency oscillator O1. The intensity of the acoustic wave is monitored by means of a sound level meter. Both frequency and intensity of the acoustic wave can be varied. A similar version of the experimental setup has been previously described in (Stoican et al., 2008) where preliminary investigations regarding the effect of the acoustic waves on the properties of the microparticles stored in a linear electrodynamic trap particle has been reported.

4. Experimental measurements

The microparticles consist of Al$_2$O$_3$ powder, 60-200 μm in diameter, stored at normal pressure and temperature. The working parameters ($U_x$, $U_z$ and $V_0$) of the linear trap were chosen so that the magnitude of the harmonic component of the photodetector output voltage $U_{ph}$
corresponding to $f_0$ to reach a maximum (Fig. 5a). This operating point of the trap is known as "spring point" (Davis et al., 1990). Two typical spectra of the voltage $U_{ph}$ recorded in these experimental conditions are shown in Fig. 6. Only frequencies less than, or equal to $3f_0/2$, have been considered because upper lines could be caused by the ac voltage $V_{ac}$ waveform imperfections or digital data processing. Also it was necessary to limit the frequency band to keep a satisfactory resolution of the recordings. As it can be seen from Fig. 6, under these conditions, without the acoustic excitation, the spectra of the photodetector output voltage contain only three significant lines, namely $f_0/2$, $f_0$ and $3f_0/2$ (here 40Hz, 80Hz and 120Hz). Depending on the applied dc voltages and photodetector position some lines could missing. Several spectra of the photodetector output voltage $U_{ph}$ recorded during acoustic excitation of the microparticles at different frequencies $f_A$ are shown in Fig. 7. The measured sound level was about 85dB. By examining the experimental records, it can be seen that the supplementary lines occur in the motional spectrum of the stored particles. As an empirical rule, the frequency peaks due to the acoustic excitation belong to the combinations of the form $f_0 \pm |f_0 - f_A|$ and $n|f_0 - f_A|$ where $n=0, 1, 2, ..., f_A$ is the frequency of the acoustic field and $f_0$ is...
the frequency of the applied ac voltage $V_{ac}$. The rule is valid both for $f_A < f_0$ and $f_A > f_0$. As seen in Fig. 7a and Fig. 7d, the two spectra are almost identical because $|f_0 - f_A|=20\text{Hz}$ in both cases. If $f_A$ is close to the $f_0$ the lowest frequency component $|f_0 - f_A|$ yields an amplitude modulation of the voltage $U_{ph}$ very clearly defined (Fig. 5b). The effect is similar to the beat signal due to the interference of two harmonic signals of slightly different frequencies.

![Fig. 7. Spectrum of the photodetector output voltage $U_{ph}$ when the stored microparticles are excited by an acoustic wave at different frequencies $f_A$. Experimental conditions: $f_0=80\text{Hz}$, $V_0=3.3\text{kV}$, $U_x=0\text{V}$, $U_z=920\text{V}$, sound level $\approx 85\text{dB}$. Experimental results.](image)

5. Numerical analysis of the stored particle motion in an acoustic field

A qualitative interpretation of the experimental results requires a numerical analysis on the motion of the stored particles. For this purpose the differential equations (5) and (6) must be numerically solved. Consequently, it is necessary to express functions $s_{Ax}(t)$ and $s_{Ay}(t)$ from (10) and (11) in terms of quantities which are known or can be experimentally measured. A body subjected to an acoustic wave field, experiences a steady force called acoustic radiation pressure and a time varying force caused by the periodic variation of the pressure in the surrounding fluid. The radiation pressure is always repulsive meaning that it is directed as the wave vector. The time varying force oscillates at the frequency of the acoustic wave and its time average is equal to zero. The radiation pressure $F_R$ exerted on a rigid spherical particle by a plane progressive wave is derived in (King, 1934) as:

$$F_R = \frac{\pi^5 d^6}{\lambda^4} \omega F \left( \rho_0 / \rho_1 \right)$$

(16)
where $d$ is the particle diameter, $\lambda$ is the wavelength of the acoustic wave and $\bar{w}$ represents the acoustic energy density. The parameter $F(\rho_0/\rho_1)$ is called relative density factor being given by:

$$F(\rho_0/\rho_1) = 1 + \frac{2}{9} \left(1 - \frac{\rho_0}{\rho_1}\right)^2 \left(2 + \frac{\rho_0}{\rho_1}\right)^2$$  (17)

where $\rho_0$ and $\rho_1$ are air and particle density, respectively. If $\rho_0/\rho_1 \ll 1$, as in the present case (see below), practically $F(\rho_0/\rho_1)=0.305$. For a plane progressive acoustic wave, energy density is (Beranek, 1993; Kinsler et al., 2000):

$$w = \frac{p^2_s}{\rho_0 c^2}$$  (18)

where $p_s$ is sound pressure and $c$ is the speed of propagation of the acoustic wave. Sound pressure can be estimated according to the formula which defines the sound pressure level SPL:

$$SPL = 20 \log_{10} \frac{p_s}{p_{ref}}$$  (19)

where $p_{ref}=2 \times 10^{-5}$N/m$^2$ is the standard reference pressure. Sound pressure level (SPL) is expressed in dB and can be experimentally measured by using sound level meters. In (King, 1934), as an intermediate result, the velocity of a spherical particle placed in an acoustic wave field is given as:

$$\frac{dr}{dt} = -\frac{A_1}{\alpha^3} k_0 \frac{\rho_0}{\rho_1} \frac{1}{F_1 - i G_1}$$  (20)

where $k_0 = \omega/c$, $\alpha = k_0 d/2$, while $\omega = 2\pi f_A$ is the angular frequency of the acoustic wave. If $\rho_0/\rho_1 \ll 1$ and $\alpha \ll 1$ then $F_1(\alpha) \simeq 2/\alpha^3$ and $G_1(\alpha) \simeq -1/3$. The quantity $A_1$ is a measure of wave intensity. Assuming a monochromatic plane progressive acoustic wave, the amplitude of the acoustic oscillating force exerted on the particle may be written:

$$F_{A0r} = |M d^2 r/dt^2| = \frac{\omega M |A_1|}{\alpha^3} k_0 \frac{\rho_0}{\rho_1} \frac{1}{F_1 - i G_1}$$  (21)

where $|A_1| = 3cv/\omega$. Taking into account expressions for $F_1, G_1, |A_1|, \alpha$ and $k_0$, written above, the relation (21) becomes:

$$F_{A0r} = 2\omega M v_0 \frac{\rho_0}{\rho_1}$$  (22)

The quantity $v$ represents the amplitude of the velocity of the surrounding fluid particles (air in this case), which are oscillating due to the acoustic wave, and is related to the sound pressure by the relation:

$$v = \sqrt{2} p_s \frac{\rho_0}{\rho_0 c}$$  (23)

Finally, the amplitude of the oscillating force, considering $\rho_0/\rho_1 \ll 1$ and $\alpha \ll 1$, is:

$$F_{A0r} = 2\sqrt{2} \omega M p_s \frac{1}{\rho_1 c}$$  (24)

Consequently:

$$F_{Ar} = F_R + F_{A0r} \cos(2\pi f_A t + \beta)$$  (25)

www.intechopen.com
As further numerical evaluations will demonstrate the acoustic radiation pressure $F_R$ is several order of magnitude less than that of oscillating force amplitude $F_{A0r}$ and has been neglected. In order to simplify theoretical analysis, the weight of the microparticles (i.e. $Mg$ where $g = 9.8 \text{m/s}^2$) has been also neglected. Experimentally, the microparticles weight are usually compensated by the electric field due to the dc voltage $U_x$. As a result, considering the experiment geometry (Fig. 4):

$$F_{Ax}(t) = F_{Ay}(t) \approx \frac{\sqrt{2}}{2} F_{A0r} \cos(2\pi f_A t + \beta)$$

Therefore the two function $s_{Ax}(t)$ and $s_{Ay}(t)$ takes form:

$$s_{Ax}(t) = s_{Ay}(t) = s_{A0} \cos(2\pi f_A t + \beta) = s_{A0} \cos(2\frac{f_A}{f_0} \xi + \beta)$$

where

$$s_{A0} = \frac{8 \omega p_s}{\rho_1 c^2 \xi}$$

All quantities existing in formula (28) are known or can be experimentally measured. The operating conditions considered for numerical analysis are summarized in Table 2. The diameter of the Al$_2$O$_3$ microparticles can vary in the range from 60$\mu$m to 200$\mu$m, as before mentioned. The two corresponding limit values of the parameters depending on the microparticles size, are shown in Table 3. The operating conditions taken into account are the same as in Table 2. According to numerical values listed in Table 2 and Table 3, $\rho_0/\rho_1 \ll 1$ and

Table 3. The limit values corresponding to the particle possible diameter. Operating conditions are listed in Table 2
α ≪1, which are in good agreement with our previous assumptions. Fourier transforms $X(f)$ and $R(f)$, of the rectangular $x(t)$ and radial $r(t) = \sqrt{x^2(t) + y^2(t)}$ coordinates, respectively, in the range from 0 to 125Hz, without the acoustic excitation, obtained by solving numerically differential equations (5) or (6), for several values of the parameters $q_{x}$, are shown in Fig.8. Fourier transforms of $x(t)$ and $y(t)$ are similar. As theory of Mathieu equations ascertains, numerical calculations shows that for $|q_{x,y}| \ll 1$, the motional spectrum contains mainly harmonic components due to the secular motion, namely $\omega_{x}/2\pi$ and $f_0 \pm \omega_{x}/2\pi$. In practice, the microparticles trapping in such conditions is difficult to be achieved because the potential barrier is too low so that weak external perturbations can eject stored particles out of the trap. The numerical results show that, close to the limit of the first stability domain, the micromotion becomes important and the motional spectrum contains only a few significant lines, namely at $f_0$ for $r(t)$ and at $f_0/2$ and $3f_0/2$ for $x(t)$, respectively. Fourier transforms $X(f)$ and $R(f)$, of the rectangular $x(t)$ and radial $r(t)$ coordinates, respectively, in the range from 0 to 125Hz, in the presence of the acoustic excitation, obtained by solving numerically differential equations (5) or (6), for several values of the acoustic wave frequency $f_{A}$, are shown in Fig. 9. Simulation conditions are listed in Table 4. Expression of the parameter $s_{A0}/R$ corresponds to $SLP$=85dB and $R$=5mm. All the remaining parameters, except acoustic wave frequency $f_{A}$, are listed in Table 2 and Table 3. The variation of the normalized time average, $\tau(t)/R$, of the coordinate $r$ as a function of acoustic wave frequency $f_{A}$ is shown in Fig 10. As on can see from this figure there are two critical frequencies of the acoustic wave, namely $f_0/2$ and $3f_0/2$, where the amplitude of the particle motion rises sharply. It is interesting to note that this very high growth of the motion amplitude does not occur for $f_{A}=f_0$. The microparticles cloud appears to form a non-linear oscillating system for which resonance frequencies occur at $pf_0/q$ with $p$ and $q$ integer (Landau & Lifshitz, 1976). The variation of the normalized time average, $\tau(t)/R$, of the coordinate $r$ as a function of $log_{10}(s_{A0}/R)$ at acoustic wave frequency $f_{A}$=120Hz is shown in Fig 11. According to (28) and (19) the parameter $s_{A0}$ may be considered a measure of the acoustic excitation because $log_{10}(s_{A0}) = log_{10}(p_{s}) + constant$ and sound pressure level $SPL$ depends on $log_{10}(p_{s})$. As on can see from this figure, beyond a threshold value, the average distance from the trap axis grows monotonically with the level of the sound pressure level. Around $s_{A0}/R \simeq 10^{-5}$ there is a threshold value where amplitude of the microparticle motion increases suddenly (the region within the green frame from Fig.11). The transition is not uniform, there are maximum and minimum values of $\tau(t)$. This phenomenon could be interpreted as so called collapse of the resonance which means that the amplitude of resonance goes to zero for some value of the perturbation amplitude (Olvera, 2001). However numerical result must be regarded with caution. Some hypothesis aimed to simplify mathematical treatment has been introduced. For example it was assumed that the parameter $\beta$ is equal to zero and it remains constant. In fact $\beta$, which signifies the phase shift between ac voltage $V_{ac}$ and acoustic wave, varies randomly because the two oscillations are produced by different generators. Further experiments are necessary to confirm theoretical assertions. All of the numerical results have been obtained by using SCILAB 5.3.1.
Fig. 8. \( X_n(f) = \frac{X(f)}{X_{\text{max}}(f)} \) (red) and \( R_n(f) = \frac{R(f)}{R_{\text{max}}(f)} \) (blue) where \( X(f) \) and \( R(f) \) are Fourier transform of the rectangular \( x(t) \) and radial \( r(t) \) coordinates, respectively, for \( 0 < f < 125 \text{Hz}, a_x = 0, f_0 = \frac{\Omega}{2\pi} = 80 \text{Hz}, \delta = 0.01 \), without the acoustic excitation. Numerical result.
Fig. 9. \( X_n(f) = X(f)/X_{\text{max}}(f) \) (red) and \( R_n(f) = R(f)/R_{\text{max}}(f) \) (blue) where \( X(f) \) and \( R(f) \) are Fourier transform of the rectangular \( x(t) \) and radial \( r(t) \) coordinates, respectively, for \( 0 < f < 125 \text{Hz} \), in the presence of the acoustic excitation, for several values of the acoustic wave frequency \( f_A \). The plots correspond to the frequency \( f_0 = 80 \text{Hz} \) of the ac supply voltage \( V_{\text{ac}} \) and to an incident sound level of 85dB. A complete list of the simulation conditions is displayed in Table 4. Numerical result.
Fig. 10. The normalized time average of the coordinate \( r(t) \) as a function of acoustic wave frequency \( f_A \). \( R \) represents the inner radius of the linear trap. Simulation conditions are displayed in Table 4. Numerical result.

Fig. 11. The normalized time average of the coordinate \( r(t) \) as a function of parameter \( s_{A0}/R \) at acoustic wave frequency \( f_A=120\text{Hz} \). Parameter \( s_{A0} \) is a measure of acoustic excitation \( (\log_{10}(s_{A0})) \sim \text{SPL} \). Simulation conditions, except parameter \( s_{A0}/R \), are displayed in Table 4. Numerical result.

6. Conclusion

Although measurements result has been interpreted using an approximative and simplified theory of the linear trap, by comparing the experimental spectra with numerical simulations a good qualitative agreement can be noticed. The spectrum of the laser radiation intensity scattered by the stored microparticles seems to be a superposition of the \( r(t) \) and \( x(t) \) (or \( y(t) \)) harmonic components, respectively. Because the experimental spectrum obtained without the acoustic excitation, shown in Fig.6 is similar to that displayed in Fig.8d we may suppose that operating point of the linear trap during the experiment corresponds to \( q_x \approx 0.908 \) (i.e. \( Q/M \approx 5.4 \times 10^{-4} \text{ C/kg cf. (8)} \)). The simulation of the stored particle motion in an acoustic wave has been done taking into account this assumption. By knowing the ratio \( Q/M \) and the mass of a microparticle (from Table 3) electric charge \( Q \) can be evaluated. Because the microparticles are stored in air at normal pressure, a supplementary restriction on the physical characteristics of the microparticles arises. Assuming that microparticles are spherical and the
electric charge is uniform distributed over its surface, the electric field $E_d$ at the surface is:

$$E_d = \frac{Q}{4\pi\epsilon_0(d/2)^2}$$

(29)

where $\epsilon_0=8.854 \times 10^{-12}$ F/m. Electric charge $Q$ results from:

$$Q = M \left( \frac{Q}{M} \right) = \frac{4\pi}{3} \left( \frac{d}{2} \right)^3 \rho_1 \left( \frac{Q}{M} \right)$$

(30)

where $Q/M$ is known. The electric field $E_d$ can not exceed a certain threshold value $E_{\text{max}}$, called dielectric strength, at which surrounding gas molecules become ionized, so that the condition $E_d < E_{\text{max}}$ is necessary. From (29) and (30), the above condition can be written:

$$d < \frac{6\epsilon_0 E_{\text{max}}}{(Q/M)\rho_1}$$

(31)

The dielectric strength $E_{\text{max}}$ varies with the shape and size of the charged body, humidity and pressure of the air. We consider here the dielectric strength of air $E_{\text{max}} \approx 3 \times 10^6$ V/m. By replacing numerical values in (31), it results that $d < 69 \mu$m. Therefore the diameter of the microparticles which produce the laser beam scattering sensed by the photodetector lies in the range 60-69 $\mu$m. Distribution of the frequency peaks are almost identical both in experimental recordings and numerical simulation, but their relative heights are different. Besides a simplified theoretical approach, there are a few possible experimental issues. The dc voltages $U_x$ and $U_z$ shift the stored microparticles cloud position relative to the trap axis and, implicitly, to the photodetector aperture. Thus, viewing angle of the photodetector is modified and some harmonic components could not be observed or appear to be very weak. On the other hand, non-uniformity of the frequency characteristic for the common loudspeakers, especially at frequencies below 100Hz, could distort experimental recordings. Numerical estimations demonstrate that, in the described experimental conditions and within the considered range of the acoustic wave frequency, the acoustic radiation pressure $F_R$ is very weak compared to the microparticles weight $Mg$ or amplitude of the oscillating force exerted by acoustic wave $F_\text{A}$ (see Table 3). Certainly, the first improvement of theoretical approach would be to add a constant term corresponding to the microparticles weights in differential equations (2) and/or (3), depending on the orientation of the reference system. Like weight, acoustic radiation pressure does not vary in time and can be regarded, mathematically speaking, as a small correction of the microparticles weight. As a result the acoustic radiation pressure is not important here, where only acoustic waves with frequency around frequency $f_0$ of the ac voltage have been investigated. The acoustic radiation pressure can become significantly at higher frequencies, (see (16)) varying according to $f^4$. On the other hand, according to the numerical results, if the intensity of the acoustic wave is larger than a threshold value and its frequency has proper values, the amplitude of the stored microparticles motion increases significantly. These frequencies are identical to certain frequency peaks existing in the motional spectrum of the stored particle predicted by the numerical simulations (Fig. 8d) and observed experimentally (Fig.6b). Therefore its action is effective only for the microparticles species whose properties meet certain conditions. In this way, theoretically, the selective manipulation of the stored microparticles by means of the acoustic waves becomes possible. We gratefully acknowledge material support provided by Mira Technologies Group SRL - Bucharest, Romania.
7. References

Acoustics is a discipline that deals with many types of fields wave phenomena. Originally the field of Acoustics was consecrated to the sound, that is, the study of small pressure waves in air detected by the human ear. The scope of this field of physics has been extended to higher and lower frequencies and to higher intensity levels. Moreover, structural vibrations are also included in acoustics as a wave phenomena produced by elastic waves. This book is focused on acoustic waves in fluid media and elastic perturbations in heterogeneous media. Many different systems are analyzed in this book like layered media, solitons, piezoelectric substrates, crystalline systems, granular materials, interface waves, phononic crystals, acoustic levitation and soft media. Numerical methods are also presented as a fourth-order Runge-Kutta method and an inverse scattering method.
