1. Introduction

The modelling and control of multiple robotic manipulators handling a constrained object requires more sophisticated techniques compared with a single robot working alone. Since the theory employed for cooperative robots is independent of their size, one can think of them as mechanical hands. The study of mechanical hands is important not only because these can be used as prosthetic devices for humans, but also because they increase considerably the manipulation capacity of a robot when substituting the usual gripper. Thus, robot hands (as well as cooperative robots), may find many areas of application nowadays. Many benefits can be obtained by using them in industrial manufacturing. A typical example is in a flexible assembly, where the robots join two parts into a product. Cooperative manipulators can also be used in material handling, e.g., transporting objects beyond the load carrying capacity of a single robot. Furthermore, their employment allows to improve the quality of tasks in the manufacturer industry that require of great precision.

On the other hand, cooperative robots are indispensable for skillful grasping and dexterous manipulation of objects. However, the literature about experimental results on the modeling, simulation and control of systems of multiple manipulators holding a common object is rather sparse.

A dynamic analysis for a system of multiple manipulators is presented in Orin and Oh (Orin & Oh 1981), where the formalism of Newton-Euler for open chain mechanisms is extended for closed chain systems. Another approach widely used is the Euler-Lagrange method (Naniwa et al. 1997). The equations of motion for each manipulator arm are developed in the Cartesian space and the impact of the closed chain is investigated when the held object is in contact with a rigid environment, for example the ground. Another general approach to obtain the dynamic model of a system of multiple robots is based on the estimation of the grasping matrix (Cole et al. 1992, Kuc et al. 1994, Liu et al. 2002, Murray et al. 1994, Yoshikawa & Zheng 1991). Here, the grasping matrix is used to couple the manipulators dynamics with that of the object, while this is
modeled by the Newton-Euler formulation. The dynamic analysis for cooperative robots with flexible joints holding a rigid object is presented in Jankowski et al. (Jankowski et al. 1993).

This work presents the study of the dynamic equations of a cooperative robot system holding a rigid object without friction. The test bed is made up of two industrial robots and it is at the Laboratory for Robotics of the National University of Mexico. The dynamic model for the manipulators is obtained independently from each other with the Lagrangian approach. Once the robots are holding the object, their joint variables are kinematically and dynamically coupled. Assuming that the coupling of the system is described by holonomic constraints, the manipulators and object equations of motion are combined to obtain the dynamic model of the whole system, which can be used for simulation purposes. It is important to stress that a robot manipulator in free motion does not have geometric constraints; therefore, the dynamic model is described by Ordinary Differential Equations (ODE). When working with constrained motion, the dynamic model is described by Differential Algebraic Equations (DAE). It is shown how the simulation of this kind of systems can be carried out, including a general approach to simulate contact forces by solving DAE’s.

Early attempts to establish a relationship between the automatic control of robots carrying out a shared task are referred to Kathib’s operational space formulation (Khatib 1987). During the 1980’s, the most important research results considered the contact evolution during manipulation (Montana 1988). Such a contact evolution requires a perfect combination of position and force control. Some of the first approaches following this objective are presented in Ly and Sastry (Li & Sastry 1989) and Cole (Cole 1990). In those works, the dynamics of the object is considered explicitly. In Parra-Vega and Arimoto (Parra-Vega & Arimoto 1996), Liu et al. (Liu et al. 1997) and Parra-Vega et al. (Parra-Vega et al. 2001), control schemes which do not take into account the dynamics of the object but rather the motion constraints are designed. These control approaches have the advantage that they do not require an exact knowledge of the system model parameters, since an adaptive approach is introduced. More recently, Schlegl et al. (Schlegl et al. 2001) show some advances on hybrid (in terms of a combination of continuous and discrete systems) control approaches.

Despite the fact that Mason and Salisbury (Mason & Salisbury 1985) proposed the base of sensor-less manipulation in the 1980’s, there are few control algorithms for cooperative robot systems which take into account the possible lack of velocity measurements. Perhaps because, since a digital computer is usually employed to implement a control law, a good approximation of the velocity vector can be obtained by means of numerical differentiation. However, recent experimental results have shown that a (digitalized) observer in a control law performs better (Arteaga & Kelly 2004). Thus, in Gudiño-Lau et al. (Gudiño-Lau et al. 2004) a decentralized control algorithm for cooperative manipulators (or robot hands) which achieves asymptotic stability of tracking of desired positions and forces by using an observer is given. In this work, a new control law based on a force filter is presented. This is a general control law, so that it can be applied to a system with more than two manipulators involved as well. The control scheme is of a decentralized architecture, so that the input torque for each robot is calculated in its own joint space and takes into account motion constraints rather than the held object dynamics. Also, an observer is employed to avoid velocity measurements and experimental results are presented to validate the theoretical results.
2. Experimental System

The system under study is made up of two industrial robots and it is at the Laboratory for Robotics of the National University of Mexico (Figure 1). They are the A465 and A255 of CRS Robotics. Even though the first one has six degrees of freedom and the second one five, only the first three joints of each manipulator are used in this case, while the rest of them are mechanically braked. Each joint is actuated by a direct current motor with optical encoders. Both manipulators have a crash protection device in the end effector and a force sensor installed on it; an aluminum finger is mounted on the sensor. The object is constituted by a melamine plastic box with dimensions 0.15m × 0.15m × 0.311m and weight 0.400kg. The experiments are performed in a Pentium IV to 1.4 GHz personal computer with two PCI-FlexMotion-6C boards of National Instruments. The sampling time is of 9ms. Controllers are programmed in the LabWindows/CVI software of National Instruments.

A schematic diagram of the robots holding an object is depicted in Figure 2. The system variables are the generalized coordinates, velocities, and accelerations, as well as the contact forces exerted by the end effector on the common rigid object, and the generalized input forces (i.e., torques) acting on the joints.

Fig. 1. Robots A465 and A255 of CRS Robotics.

To describe the kinematic relationships between the robots and the object, a stationary coordinate frame $C_0$ attached to the ground serves as reference frame, as shown in Figure 2. An object coordinate frame $C_2$ is attached at the center of mass of the rigid object. The origin of the coordinate frame $C_1$ is located at the center of the end effector of robot A465. In the same way, the origin of the coordinate frame $C_3$ is located at the
center of the end effector of robot A255. The coordinate frame $C_0$ has been considered to be the inertial frame of the whole system. $\mathbf{p}_i$ is the position vector of the object center of mass expressed in the coordinate system $C_0$. $\mathbf{p}_1$ and $\mathbf{p}_2$ are vectors that describe the position of the contact points between the end effectors of robots A465, A255 and the object, respectively, expressed in the coordinate system $C_0$ (Gudiño-Lau & Arteaga 2005).

![Fig. 2. Schematic diagram of robots holding an object.](image)

3. The Cooperative Robots Dynamic Model

Consider the cooperative system with two robot arms shown in Figure 1, each of them with $n_i = 3$ degrees of freedom and $m_i = 1$ constraints arising from the contact with the held object. Then, the total number of degrees of freedom is given by $n = \sum_n n_i$ with a total number of $m = \sum_m m_i$ constraints.

3.1 Dynamic model with constraint motion and properties

The dynamic model for each individual manipulator, $i=1,2$, is obtained by the Lagrange's formulation as (Parra-Vega et al. 2001)

$$H_i(q_i)\ddot{q}_i + C_i(q_i, \dot{q}_i)\dot{q}_i + D_i\dot{q}_i + g_i(q_i) = \tau_i + \lambda_i^T(q_i)\dot{q}_i,$$

(1)

where $q_i \in \mathbb{R}^n$ is the vector of generalized joint coordinates, $H_i(q) \in \mathbb{R}^{n \times n}$ is the symmetric positive definite inertia matrix, $C_i(q, \dot{q}) \in \mathbb{R}^{n \times n}$ is the vector of Coriolis and centrifugal torques, $g_i(q) \in \mathbb{R}^n$ is the vector of gravitational torques, $D_i \in \mathbb{R}^{n \times n}$ is the positive semidefinite diagonal matrix accounting for joint viscous friction coefficients, $\tau \in \mathbb{R}^n$ is the vector of generalized torques acting at the joints, and $\lambda \in \mathbb{R}^m$ is the vector of Lagrange multipliers (physically represents the force applied at the contact point). $\lambda_i^T(q_i)\dot{q}_i$ represents the interaction of the rigid object with the two manipulators. $\lambda_i(q) \in \mathbb{R}^m$ is assumed to be full rank in this paper. $g(q)$ denotes the gradient of the object surface vector $g \in \mathbb{R}^n$, which maps a vector onto the normal plane at the tangent plane that arises at the contact point described by...
\[ \Phi(q_i) = 0, \]  

(2)

Equation (2) is a geometrical constraint expressed in an analytical equation in which only position is involved and that does not depend explicitly of time \( t \). Constraints of this form are known as holonomic constraints (they are also classified as sclero-holonomic).

Note that equation (2) means that homogeneous constraints are being considered (Parra-Vega et al. 2001). The complete system is subjected to 2 holonomic constraints given by

\[ \Phi(q) = 0, \]

(3)

where \( \Phi(q) = \Phi(q_i, q_j) \in \mathbb{R}^n \). This means that the object being manipulated and the environment are modeled by the constraint (3). If the holonomic constraints are correctly calculated, then the object will remain hold.

Let us denote the largest (smallest) eigenvalue of a matrix by \( \lambda_{\min}(*) \). The norm of an \( n \times 1 \) vector \( x \) is defined by \( |x| = \sqrt{x^T x} \) while the norm of an \( m \times n \) matrix \( A \) is the corresponding induced norm \( |A| = \lambda_{\max}(A) \).

By recalling that revolute joints are considered, the following properties can be established (Liu et al. 1997, Arteaga Pérez 1998, Parra-Vega et al. 2001):

**Property 3.1.** Each \( H_i(q_i) \) satisfies

\[ \lambda_\min(H_i) \leq x^T H_i(q_i) x \leq \lambda_\max(H_i) \quad \forall q_i, \quad \forall x \in \mathbb{R}^n \]

where \( \lambda_\min \leq \lambda_\max \). \( \lambda_\min \leq \lambda_\max \) and \( 0 < \lambda_\min \leq \lambda_\max < \infty \).

**Property 3.2.** With a proper definition of \( C_i(q_i, \dot{q}_i) = H_i(q_i) - 2C_i(q_i, \dot{q}) \) is skew-symmetric.

**Property 3.3.** The vector \( C_i(q_i, x) y \) satisfies \( C_i(q_i, x)y = C_i(q,i) x \forall x, y \in \mathbb{R}^n \).

**Property 3.4.** It is satisfied

\[ \| C_i(q_i, x) \| \leq k_1 \| x \| \quad \forall \| x \| < k_2, \forall x \in \mathbb{R}^n \]

**Property 3.5.** The vector \( \dot{q}_i \) can be written as

\[ \dot{q}_i = \dot{q}_i + (I_i^*, I_i J_i, \dot{q}_i, I_i^*, \dot{q}) \]

\[ = (1, i_1, i_2, \dot{q}_i, I_i J_i, \dot{q}) \]

\[ = Q_i(q_i, \dot{q}_i)^* (I_i^*, I_i J_i, \dot{q}_i) \]

(4)

where \( I_i^*, I_i J_i \in \mathbb{R}^{n \times n} \) stands for the Penrose’s pseudoinverse and \( Q_i \in \mathbb{R}^{n \times n} \) satisfies rank \( (Q_i) = n_i - m_i \). These two matrices are orthogonal, i.e. \( Q_i J_i^* = 0 \) (and \( Q_i^* J_i = 0 \)). \( \dot{q} \) is the so called constrained velocity. Furthermore, in view of constraint (3), it holds

\[ \sum_{i=1}^{l} p_i = 0 \quad \text{and} \quad \sum_{i=1}^{l} \dot{p}_i - \sum_{i=1}^{l} \int_{p_0}^{p_i} \dot{q} \, dt = 0 \]

(5)

Since homogeneous constraints are being considered, it also holds in view of (2) that

\[ \dot{p}_i = 0 \quad \text{and} \quad p_i = 0 \]

(6)

for \( i = 1, \ldots, l \). \( p_i \) is called the constrained position.

As shown in Liu et al. (Liu et al. 1997), if we consider homogeneous holonomic constraints we can write the constrained position, constrained velocity and constrained acceleration as

\[ \Phi(q_i) = 0 \]

(7)

\[ \Phi(q) = J_\alpha(q_i) \dot{q}_i = 0 \]

(8)

\[ \Phi(p) = J_\alpha(q_i) \dot{p}_i + J_\alpha(q_i) \dot{q}_i = 0 \]

(9)

respectively. Recall that in our case \( n_i = 3, n = 6, m_i = 1, \) and \( m = 2, i=1,2 \).
3.2 Dynamic model of the rigid object

The motion of the two robot arms is dynamically coupled by the generalized contact forces interacting through the common rigid object. To describe this interaction, it is necessary to know the object dynamics. According to the free body diagram of Figure 3, Newton’s equation of motion are

\[
 m \ddot{\mathbf{x}}_o - m \mathbf{g}_o = f_1 - f_2,
\]

(10)

where \( m \in \mathbb{R}^{3 \times 3} \) is the diagonal mass matrix of the object, \( \dot{\mathbf{x}}_o \in \mathbb{R}^3 \) is the vector describing the translational acceleration of the center of mass of the rigid object, \( f_1 \in \mathbb{R}^3 \) and \( f_2 \in \mathbb{R}^3 \) are forces exerted by the robots, and \( \mathbf{g}_o \in \mathbb{R}^3 \) is a gravity vector. All vectors are expressed with reference to the inertial coordinate frame \( C_0 \). The contact forces vector are given by

\[
 f_i = n_i \lambda_i,
\]

(11)

where \( n_i \in \mathbb{R}^3 \) represents the direction of the force (normal to the constraint) and \( \lambda_i \in \mathbb{R} \) given in (1).

Fig. 3. Force free body diagram.

The following assumptions are made to obtain the dynamic model for the cooperative system and to design the control-observer scheme:

Assumption 3.1 The end effectors (fingers) of the two robot arms are rigid.

Assumption 3.2 The object is undeformable, and its absolute and relative position are known.

Assumption 3.3 The kinematics of each robot is known.

Assumption 3.4 The \( l \) robots of which the system is made up satisfy constraints (2) and (6) for all time. Furthermore, none of the robots is redundant and they do not reach any singularity.

Assumption 3.5 The matrix \( J_{\omega} \) is Lipschitz continuous, i.e.

\[
 \| J_{\omega}(q_i) - J_{\omega}(q_o) \| \leq L \| q_i - q_o \|
\]

(12)

for a positive constant \( L \) and for all \( q_i, q_o \in \mathbb{R}^n \). Besides, there exist positive finite constants \( c_{0i} \) and \( c_{1i} \) which satisfies
Note that Assumption 3.4 is a common one in the field of cooperative robots. None of the robots can be redundant that (2) is satisfied only by a bounded vector $q_i$. On the other hand, the closed kinematic loop that arises when the manipulators are holding an object is redundant. Assumption 3.5 is quite reasonable for revolute robots, since the elements of $q_i$ appear as argument of sines and cosines functions. This is why (13)-(14) is valid.

### 3.3 Dynamic coupling

The position, velocity and acceleration of the object center of mass with reference to the inertial coordinated frame are given in Cartesian coordinates by:

$$
\begin{align*}
\mathbf{x}_o &= h_i(q_i) \\
\mathbf{x}_o &= J_{o}(q_i)\mathbf{q}_i \\
\ddot{\mathbf{x}}_o &= J'_{o}(q_i)\dot{\mathbf{q}}_i + J^T_{o}(q_i)\dot{\mathbf{f}}_i,
\end{align*}
$$

respectively, with $i = 1, 2$. $h_i(q_i) \in \mathbb{R}^n$ is the forward kinematics of the center of mass of the object expressed in the coordinate system $C_i$, and $J_i(q_i) \in \mathbb{R}^{n \times n}$ is the corresponding Jacobian matrix of $h_i(q_i)$. Substituting (17) into (10) yields

$$
m_i J_{o}(q_i)\dot{\mathbf{q}}_i + m_i J_{o}(q_i)\mathbf{q}_i = \mathbf{f}_i - \mathbf{f}_2.
$$

Now, consider writing (1) as (Murray et al. 1994)

$$
H_i(q_i)\dot{\mathbf{q}}_i + C_i(q_i,\dot{\mathbf{q}}_i)\dot{\mathbf{q}}_i + D_i\mathbf{q}_i + g_i(q_i) = \mathbf{r}_i + J^T_i(q_i)\mathbf{f}_i.
$$

Note that

$$
J^T_i(q_i) = J^T_i(q_i)m_i,
$$

in view of (11). $J_i(q_i)$ is the manipulator analytical Jacobian. On the other hand, from (18) one gets

$$
f_i = m_i J_{o}(q_i)\dot{\mathbf{q}}_i + m_i J_{o}(q_i)\mathbf{q}_i - m_i g_i + \mathbf{f}_i.
$$

Then, for $i=1$ in (19) one gets

$$
H_i(q_i)\dot{\mathbf{q}}_i + C_i(q_i,\dot{\mathbf{q}}_i)\dot{\mathbf{q}}_i + D_i\mathbf{q}_i + g_i(q_i) = \\
\mathbf{r}_i + J^T_i(q_i)m_i J_{o}(q_i)\dot{\mathbf{q}}_i + m_i J_{o}(q_i)\mathbf{q}_i - m_i g_i + \mathbf{f}_i = \\
\mathbf{r}_i + J^T_i(q_i)m_i J_{o}(q_i)\dot{\mathbf{q}}_i + J^T_i(q_i)m_i J_{o}(q_i)\mathbf{q}_i - J^T_i(q_i)m_i g_i + J^T_i(q_i)\mathbf{f}_i,
$$

or

$$
\mathbf{r}_i + J^T_i(q_i)\mathbf{f}_2 = (H_i(q_i) - J^T_i(q_i)m_i J_{o}(q_i))\dot{\mathbf{q}}_i + \\
(\mathbf{r}_i + J^T_i(q_i)m_i J_{o}(q_i)\mathbf{q}_i - J^T_i(q_i)m_i g_i + J^T_i(q_i)\mathbf{f}_i)\dot{\mathbf{q}}_i + g_i(q_i) + J^T_i(q_i)m_i g_i.
$$

By defining
one finally gets

\[ H_{11}(q_1) \ddot{q}_1 + C_{11}(q_1, \dot{q}_1) \dot{q}_1 + g_{11}(q_1) = \tau_1 + J_{11}^T(q_1) f_1. \]  

(27)

In the same fashion, we make the analysis for the robot A255, to get

\[ H_{22}(q_2) \ddot{q}_2 + C_{22}(q_2, \dot{q}_2) \dot{q}_2 + g_{22}(q_2) = \tau_2 + J_{22}^T(q_2) f_2, \]  

(28)

with

\[ H_{11}(q_1) \ddot{q}_1 + C_{11}(q_1, \dot{q}_1) \dot{q}_1 + g_{11}(q_1) = \tau_1 + J_{11}^T(q_1) f_1, \]  

(29)

\[ H_{22}(q_2) \ddot{q}_2 + C_{22}(q_2, \dot{q}_2) \dot{q}_2 + g_{22}(q_2) = \tau_2 + J_{22}^T(q_2) f_2, \]  

(30)

\[ g_{11}(q_1) = g_{11}(q_1) + J_{11}^T(q_1) m_1 q_1. \]  

(31)

The dynamic models in (27)-(28) describe the motion of the entire closed chain, where each individual manipulator represents a subsystem coupled to the other one through kinematic and dynamic constraints.

### 3.4 Force modeling for cooperative robots

A robot manipulator in free motion does not have geometric constraints; therefore, the dynamic model is described by Ordinary Differential Equations (ODE). When working with constrained motion, there appear holonomic constraints; for this reason, the dynamic model is described by Differential Algebraic Equations (DAE). To simulate contact forces, DAE’s must be solved. First of all, from the dynamic model for cooperative robots (1), we obtain

\[ \ddot{q} = H(q) \left( \tau + J^T(q) \lambda + C(q, \dot{q}) \dot{q} - D \dot{q} - g(q) \right) \]  

(32)

However, (7)-(9) must hold as well. Substituting the right hand side of (32) into (9) yields

\[ \phi(q) = I(q) \left[ H(q) (\tau + J^T(q) \lambda + C(q, \dot{q}) \dot{q} - D \dot{q} - g(q)) \right] \]  

(33)

\[ + \dot{J}^T(q) \ddot{q}, \]  

\[ = I(q) H(q) (\tau + J^T(q) \lambda + C(q, \dot{q}) \dot{q} - D \dot{q} - g(q)) \]  

\[ + \dot{J}^T(q) \ddot{q}, \]  

\[ = 0. \]  

From the previous equation we obtain

\[ \lambda = \left( I(q) H(q) (\tau + J^T(q) \dot{q}) \right)^{-1} \left[ \phi(q) - \dot{J}^T(q) \ddot{q} \right] \]  

(34)

The system described by (11), (27)-(28) and (34) could now be simulated as second order differential equations. However, the inclusion of the constraints in the form (34) does not guarantee the convergence of the contact velocity and position constraints to zero. This is because \( \phi(q) = 0 \) represents a double integrator. Thus, any small
difference of \( \varphi(q_i) \) or \( \dot{\varphi}(q_i) \) from zero in (7)-(9) will diverge. This problem has been successfully addressed by the constraint stabilization method in the solution of DAE’s (Baumgarte 1972).

According to this approach, the constraints are asymptotically stabilized by using

\[
\ddot{\varphi}(q_i) + 2 \alpha \varphi(q_i) + \beta \dot{\varphi}(q_i) = 0, \tag{35}
\]

instead of \( \ddot{\varphi}(q_i) = 0 \) and \( \beta_i \) are chosen appropriately to ensure the fast convergence of both the constraint position \( \varphi(q_i) \) and velocity constraint \( \dot{\varphi}(q_i) \) to zero (in case of offset). Equations (11), (27)-(28) and (34)-(35) fully describe the motion of the system to be simulated (Gudiño-Lau & Arteaga 2005).

4. Control with velocity estimation

4.1 Control Law

In this section, a linear filter for the force error and the tracking control problem of a cooperative system of rigid robots are studied. Consider model (1) and define the tracking and observation errors as

\[
\hat{q}_i \triangleq q_i - q_{ii}, \tag{36}
\]
\[
z_i \triangleq q_i - z_i, \tag{37}
\]

where \( q_{ii} \) is a desired smooth bounded trajectory satisfying constraint (2), and \( \hat{q}_i \) represents the estimated value of \( q_i \). Other error definitions are

\[
\Delta p_i \triangleq p_i - p_{ii}, \tag{38}
\]
\[
\Delta \lambda_i \triangleq \lambda_i - \lambda_{ii}, \tag{39}
\]

where \( p_{ii} \) is the desired constrained position which satisfies (6). \( \lambda_{ii} \) is the desired force to be applied by each finger on the constrained surface. Other useful definitions are

\[
\hat{\Delta} p_i \triangleq \hat{p}_i - \Delta p_{ii} - \beta \Delta \lambda_i + \xi_i \phi + \xi_i \Delta \lambda_i, \tag{40}
\]

\[
\hat{\Delta} \lambda_i \triangleq \hat{\lambda}_i - \Delta \lambda_{ii}, \tag{41}
\]

\[
\lambda_{ii} = \int_{\theta_{\min}}^{\theta_{\max}} \Delta \lambda_i (\theta) d\theta, \tag{42}
\]

where \( \lambda_{ii} = k_i \in \mathbb{R}^{+\infty} \) with \( k_i > 0 \), and \( \xi_i, \xi_i \in \mathbb{R}^{+\infty} \) are diagonal positive definite matrices, and \( \beta_i \) is a positive constant. To get (41) the equality \( \hat{q}_i - q_{ii} = z_i - \hat{z}_i \) has been used. Note also that \( s_{pi} \) and \( s_{ii} \) are orthogonal vectors. \( \phi_i \in \mathbb{R}^{+\infty} \) is the output of the linear filter given by

\[
\dot{w}_i = -A_i w_i + \Delta \lambda_i, \tag{43}
\]
\[
\phi_i = B_i w_i. \tag{44}
\]

\( A_i, B_i \in \mathbb{R}^{+\infty} \) are diagonal positive definite matrices and \( w_i \in \mathbb{R}^{+\infty} \) is the state for the filter. Also, we define

\[
\zeta_i \triangleq \dot{\phi}_i = -B_i A_i w_i + B_i \Delta \lambda_i = -A_i \phi_i + B_i \Delta \lambda_i. \tag{45}
\]
Now, let us analyze $q_i$. This quantity is given by

$$\ddot{q}_i = Q_i(q_i)(\ddot{q}_i - \Lambda_i(\dot{q}_i - \dot{q}_i)) + \int_0^t q_i(\dot{p}_i - \beta_i(\dot{p}_i - \dot{p}_i) + \frac{\xi}{q_i} + \frac{\xi_i}{\Delta t})$$

As it will be shown later, $q_i$ is necessary to implement the controller and the observer. However, this quantity is not available since $q_i$ is not measurable. In order to overcome this drawback, let us consider $Q_i(q_i) \in \mathbb{R}^{n_i \times n_i}$. Then you have

$$\dot{Q}_i(q_i) = \begin{bmatrix}
\frac{\partial a_{11}(q_i)}{\partial q_i} q_i & \ldots & \frac{\partial a_{1n_i}(q_i)}{\partial q_i} q_i \\
\vdots & \ddots & \vdots \\
\frac{\partial a_{n_i1}(q_i)}{\partial q_i} q_i & \ldots & \frac{\partial a_{nn_i}(q_i)}{\partial q_i} q_i
\end{bmatrix},$$

where $a_{i\beta}$ is the $\alpha \beta$ element of $Q_i(q_i)$. Based on (47), consider the following definition

$$\dot{Q}_i(q_i) = \begin{bmatrix}
\frac{\partial a_{11}(q_i)}{\partial q_i} \dot{q}_i & \ldots & \frac{\partial a_{1n_i}(q_i)}{\partial q_i} \dot{q}_i \\
\vdots & \ddots & \vdots \\
\frac{\partial a_{n_i1}(q_i)}{\partial q_i} \dot{q}_i & \ldots & \frac{\partial a_{nn_i}(q_i)}{\partial q_i} \dot{q}_i
\end{bmatrix},$$

with

$$\dot{q}_i = \dot{q}_i - \Lambda_i z_i.$$ (49)

Then, one can compute

$$\dot{Q}_i(q_i) = Q_i(q_i) - \dot{Q}_i(q_i) = \begin{bmatrix}
\frac{\partial a_{11}(q_i)}{\partial q_i} r_i & \ldots & \frac{\partial a_{1n_i}(q_i)}{\partial q_i} r_i \\
\vdots & \ddots & \vdots \\
\frac{\partial a_{n_i1}(q_i)}{\partial q_i} r_i & \ldots & \frac{\partial a_{nn_i}(q_i)}{\partial q_i} r_i
\end{bmatrix},$$

where

$$r_i = \dot{q}_i - \dot{q}_i = \dot{z}_i + \Lambda_i z_i.$$ (51)

In view of (48), we propose the following substitution for $\tilde{q}_i$

$$\tilde{q}_i = Q_i(q_i)(\ddot{q}_i - \Lambda_i(\dot{q}_i - \dot{q}_i)) + \int_0^t q_i(\dot{p}_i - \beta_i(\dot{p}_i - \dot{p}_i) + \frac{\xi}{q_i} + \frac{\xi_i}{\Delta t})$$

$$+ \dot{Q}_i(q_i)(\ddot{q}_i - \Lambda_i(\dot{q}_i - \dot{q}_i)) + \int_0^t q_i(\dot{p}_i - \beta_i(\dot{p}_i - \dot{p}_i) + \frac{\xi}{q_i} + \frac{\xi_i}{\Delta t}),$$

where $j_i(q_i)$ is defined in the very same fashion as $Q_i(q_i)$ in (48). Note that $\dot{p}_i$ is still used since this value is known from (6). After some manipulation, it is possible to get

$$\tilde{q}_i = \dot{q}_i + e_i(r_i).$$ (53)
where

\[ e_i(r) \triangleq \hat{\mathbf{Q}}_i(q_i) (\dot{q}_i - \Lambda_i \dot{q}_i + \Delta_i z_i) + \mathbf{I}^T_i(q_i) \left( \dot{p}_i - \beta_i \Delta p + \mathbf{g}_i + \xi_i \Delta \mathbf{F} \right) \]  

The proposed controller is then given for each single input by

\[ r_i \triangleq - H_i(q_i) \dot{q}_i + C_i(q_i, \dot{q}_i) \dot{q}_i + D_i \dot{q}_i + g_i(q_i) - K_{ni}(q_i, \dot{q}_i) - \mathbf{J}^T_i(q_i) \left( \mathbf{A}_n + B_i^T \zeta_i - K_{ni} \Delta \mathbf{F} \right), \]  

where \( K_{ni} \in \mathbb{R}^{m \times m}, K_{ni} \in \mathbb{R}^{m \times m} \) are diagonal positive definite matrices. Note that from (41) and (51) it is

\[ q_i - q_i = s_i - r_i. \]

Thus, from (53) one gets

\[ r_i = H_i(q_i) (\dot{q}_i + e_i(r)) + C_i(q_i, \dot{q}_i) \dot{q}_i + D_i \dot{q}_i + g_i(q_i) - K_{ni}(q_i, \dot{q}_i) - \mathbf{J}^T_i(q_i) \left( \mathbf{A}_n + B_i^T \zeta_i - K_{ni} \Delta \mathbf{F} \right). \]  

By substituting (56) into (1), the closed loop dynamics becomes

\[ H_i(q_i) \dot{\mathbf{s}}_i = - C_i(q_i, \dot{q}_i) \dot{\mathbf{s}}_i - K_{ni} \dot{\mathbf{s}}_i + \mathbf{J}^T_i(q_i) \left( \mathbf{B}_i^T \mathbf{A} \mathbf{\dot{\phi}} + K_{ni} \Delta \mathbf{F} \right) - C_i(q_i, \dot{q}_i) \dot{\mathbf{s}}_i + H_i(q_i) e_i(r_i) \]

after some manipulation, where \( K_{ni} \triangleq K_{ni} + D_i. \) In order to get (57), Property 3.3 has been used.

### 4.2 Observer definition

The proposed dynamics of the observer is given by

\[
\begin{align*}
\dot{\mathbf{q}}_i &= \mathbf{\ddot{q}}_i + \Lambda_i \mathbf{z}_i + k_{di} \mathbf{z}_i, \quad \text{(58)} \\
\dot{\mathbf{q}}_{\hat{i}} &= \mathbf{\ddot{q}}_{\hat{i}} + k_{di} \mathbf{\dot{z}}_i, \quad \text{(59)}
\end{align*}
\]

where \( k_{di} \) is a positive constant. This observer is simpler than the one given in (Gudiño-Lau et al. 2004), where the inverse of the inertia matrix and force measurements are required.

Since from (58) you have \( \mathbf{\dot{q}}_{\hat{i}} = \mathbf{\ddot{q}}_{\hat{i}} - \Lambda_i \mathbf{z}_i - k_{di} \mathbf{\dot{z}}_i, \) (59) becomes

\[ \mathbf{s}_i = \mathbf{r}_i + k_{di} \mathbf{\dot{r}}_i + e_i(r_i), \]

in view of (53). By multiplying both sides of (60) by \( H_i(q_i), \) and by taking into account (57), one gets

\[ H_i(q_i) \mathbf{r}_i = - H_{di} \mathbf{r}_i - C_i(q_i, \dot{q}_i) \dot{\mathbf{s}}_i - C_i(q_i, \dot{q}_i) \dot{\mathbf{s}}_i - K_{ni} \dot{\mathbf{s}}_i + \mathbf{J}^T_i(q_i) \left( \mathbf{B}_i^T \mathbf{A} \mathbf{\dot{\phi}} + K_{ni} \Delta \mathbf{F} \right), \]

where \( H_{di} \triangleq H_i(q_i) - K_{ni}. \) Finally, by using Property 3.3 again and some manipulation, it is

\[ H_i(q_i) \mathbf{r}_i = - C_i(q_i, \dot{q}_i) \mathbf{r}_i - H_{di} \mathbf{r}_i + C_i(q_i, \dot{q}_i) \dot{\mathbf{s}}_i + K_{ni} \dot{\mathbf{s}}_i - C_i(q_i, \dot{q}_i) \dot{\mathbf{s}}_i + \mathbf{J}^T_i(q_i) \left( \mathbf{B}_i^T \mathbf{A} \mathbf{\dot{\phi}} + K_{ni} \Delta \mathbf{F} \right). \]

Now, let us define

\[ \mathbf{\chi}_i \triangleq \begin{bmatrix} \mathbf{s}_i^T & \mathbf{r}_i^T & \Delta \mathbf{F}^T & \mathbf{\dot{\phi}}_i^T \end{bmatrix}, \]

as state for (42), (45), (57) and (62). The main idea of the control-observer design is to show that whenever \( \| \mathbf{\chi}_i \| \) tends to zero, the tracking errors \( \mathbf{\hat{q}}_i, \mathbf{\hat{q}}_{\hat{i}}, \Delta \mathbf{p}_i, \Delta \mathbf{p}_{\hat{i}}, \) and \( \Delta \mathbf{\lambda}_i, \) and the
observation errors $z_i$ and $\dot{z}_i$ will do it as well. From (51), this is rather obvious for $z_i$ and $\dot{z}_i$. However, it is not clear for the other variables. The following lemma shows that this is indeed the case under some conditions.

**Lemma 4.1** If $x_i$ is bounded by $x_{\text{max}}$ and tends to zero, then the following facts hold:

a) $\Delta p_i$ and $\Delta \dot{p}_i$ remain bounded and tend to zero

b) $\dot{q}_i$ and $\dot{\dot{q}}_i$ remain bounded. Furthermore, if the bound $x_{\text{max}}$ for $\|x_i\|$ is chosen small enough so as to guarantee that $\|\dot{q}_i\| \leq \eta_i$ for all $t$, with $\eta_i$ a positive and small enough constant, then both $\dot{q}_i$ and $\dot{\dot{q}}_i$ will tend to zero as well.

c) If, in addition, the velocity vector $\ddot{q}_i$ is bounded, then $\Delta \ddot{p}_i$ will tend to zero as well.

The proof of Lemma 4.1 can be found in Appendix B. It is interesting to note that, if $\|x_i\|$ is bounded by $x_{\text{max}}$, then it is always possible to find a bound for $e_i(r)$ in (54) which satisfies

$$\|e_i(r)\| \leq M, \quad \text{for all } t, \quad \text{satisfying (54).}$$

Consider now the following function

$$V(x) = \frac{1}{2} x^T M x,$$

where $M_i \triangleq \text{block diag} \{H_i(q_i), R_i\}$ and

$$R_i \triangleq \begin{bmatrix} N_i B_i^{-1} & -N_i \\ -N_i & N_i B_i \end{bmatrix},$$

with $N_i \triangleq (\bar{\xi}_i B_i A_i + \bar{\xi}_i K_i)A_i^{-1}$. In Appendix C it is shown that $V(x)$ is a positive definite function. Suppose that one may find a region

$$\mathcal{D}_i = \{ x : \|x\| \leq x_{\text{max}} \},$$

so that for all time $V(x) \leq 0$ with $V(x) = 0$ if and only if $x = 0$. If $x_{\text{max}}$ is small enough in the sense of Lemma 4.1, then from the former discussion one can conclude the convergence to zero of all error signals. The following theorem establishes the conditions for the controller-observer parameters to guarantee this.

**Theorema 4.1** Consider the cooperative system dynamics given by (1), (2) and (6), in closed loop with the filter (43)-(45), the control law (55) and the observer (58)-(59), where $q_{di}$ and $p_{di}$ are the desired bounded joint and constrained positions, whose derivatives $\dot{q}_{di}$, $\ddot{q}_{di}$, $\dot{r}_{di}$ and $\ddot{r}_{di}$ are also bounded, and they all satisfy constraint (6). Consider also 1 given regions defined by (67) for each subsystem, where the bounds $x_{\text{max}}$, $i = 1, \ldots, l$, are chosen according to

$$x_{\text{max}} \leq \frac{\eta_i a_i}{(1 + c_i (\lambda_{\text{max}}(\bar{\xi}_i) + \lambda_{\text{max}}(\bar{\xi}_i)) + \sqrt{n})},$$

where $\eta_i$ and $a_i$ are positive parameters.
with $\alpha_i$ defined in Appendix B. Then, every dynamic and error signal remains bounded and asymptotic stability of tracking, observation and force errors arise, i.e.

$$
\lim_{t \to \infty} \dot{q}_i = 0 \quad \lim_{t \to \infty} \dot{\dot{q}}_i = 0 \quad \lim_{t \to \infty} z_i = 0 \quad \lim_{t \to \infty} \dot{z}_i = 0 \quad \lim_{t \to \infty} \Delta \lambda_i = 0,
$$

if the following conditions are satisfied

$$
\lambda_{\min}(K_{ii}) \geq \mu_i + 1 + \delta_i
$$

(70)

$$
k_{ii} \geq \frac{\lambda_{\max}(K_{ii}) + w_i}{\lambda_{ii}}
$$

(71)

$$
\lambda_{\min}(E_i) \geq \delta_i + 1
$$

(72)

$$
\lambda_{\min}(\xi K_{ii}) \geq \delta_i + 1,
$$

(73)

where $w_i = \mu_i + \frac{1}{4}(\lambda_{ii} + \mu_i + \mu_i)^2 + \frac{1}{4}c_i^2\delta_i^2 + \frac{1}{4}c_i^2 \lambda_{\max}(K_{ii})$, $E_i = \xi B_i^1 A + \xi B_i^2 A + \xi K_{ii} B_i^1$, $\delta_i$, a positive constant and $\mu_i$, $\mu_i$, $\mu_i$, $\mu_i$, $\lambda_{\alpha_i}$ defined in Appendix D.

The proof of the Theorem 4.1 can be found in Appendix D.

Remark 4.1 The result of Theorem 4.1 is only local. Also, it is rather difficult to find analytically a region of attraction, but it should be noticed that it \{it cannot\} be made arbitrarily large. This is to guarantee the convergence to zero of the tracking errors $\hat{\dot{q}}_i$ and $\dot{\dot{q}}_i$. However, this does not represent a serious drawback since for grasping purposes it is usual to give smooth trajectories with zero initial position errors. On the other hand, it is worthy pointing out that a controller-observer scheme is implemented for every robot separately, while only the knowledge of each constraint of the form (2) is required.

5. Simulation and Experimental Results

In this section, some simulation results are presented. To test the accuracy of the modeling approach, experimental results are carried out as well. To protect the manipulators of the cooperative system against possible damages, the position/force control law (55) has been used for validation purposes, the motors dynamics has to be taken into account. For the object equation of motion given in (10), it is $m=I_{\text{obj}}$, $m_{\text{obj}}=0.400\text{kg}$, and $g^T_0 = \left[ g_z \ g_y \ g_x \right] = \left[ 0 \ 0 \ -9.81\text{m}/\text{s}^2 \right]$. The object dimensions are $0.15\text{m} \times 0.15\text{m} \times 0.311\text{m}$. In (35) one has $\alpha_i = 10$ and $\beta_i = 100$. The robots models are given in Appendix A.

The palm frame of the whole system is at the base of the robot A465, with its $x$-axis pointing towards the other manipulator. The task consists in lifting the object and pushing with a desired force, so that the constraints in Cartesian coordinates are simply given by

$$
q_i = x_i - b_i = 0,
$$

(74)

for $i = 1, 2$ and $b_i$ a positive constant. The desired trajectories are given by
Note that the inverse kinematics of the manipulators has to be employed to compute \( q_{di} \). These trajectories are valid from an initial time \( t_i = 10s \) to a final time \( t_f = 70s \). Before \( t_i \) and after \( t_f \), the robots are in free motion. \( w \) is a fifth order polynomial designed to satisfy \( w(t_i) = w(t_f) = 0 \). The derivatives of \( w \) are also zero at \( t_i \) and \( t_f \). By choosing (75)-(77), the robots will make a circle in the \( yz \)-plane. The only difference between the trajectories for robots A465 and A255 is the width of the object. Also, no force control is carried out until the manipulators are in the initial position to hold the object, at \( (0.554,0,0.510)[m] \) for the first manipulator and \( (0.865,0,0.510)[m] \) for the second one. The desired pushing forces are then given from \( t = t_i = 10s \) to \( t = t_f = 70s \) by.

\[
\begin{align*}
    f_{ax,1,2} &= 15(t-t_i)/10[N] & t_i \leq t < 20s \\
    f_{ax,1,2} &= 15+5 \sin(3\pi(t-20)/40)[N] & 20 \leq t < 60s \\
    f_{ax,1,2} &= 15-7.5(t-60)/10[N] & 60 \leq t < t_f
\end{align*}
\]

and \( f_{bx,1,2} = f_{bx,1,2} = 0[N] \). Note that, for simplicity, the desired forces are expressed in the base coordinate frame of each robot.

The controller has also been digitalized for the simulation. The experiment lasts 80s. The object is held at \( t=10s \). Before, the robots are in free movement and the control law (55) and the observer (58)-(59) are used with the force part set to zero (i.e. \( Q = I \) and \( M = 0 \)). It is rather easy to prove that this scheme is stable for unconstrained motion. From \( t=10s \) to \( t=70s \) it is switched on, i.e., the complete control-observer force scheme is employed only during this period of time. From \( t=70s \) to \( t=80s \) the robots go back to their initial positions in free motion. From \( t=10s \) to \( t=15s \) they begin pushing at their initial positions to hold the object, and from \( t=15s \) to \( t=20s \) they lift it to the position where the circle will be made. From \( t=20s \) to \( t=60s \) this is done while the desired force is changed for a sinus signal, as can be seen in Figure 6. Note that our purpose is to show that simulation results of the constrained system are acceptable by using the approach described in Section 3. For this reason, the desired forces (or positions) are not shown. Only the real and simulated signals are presented. As can be seen, there is a good match. Of course, simulation results are free of noise. Note also that, since we have not proposed any special method to simulate the moment when the object is held, i.e., when the robots change from free to constrained motion, there is a peak at \( t=10s \) in the simulation. From \( t=60s \) to \( t=65s \) the object is put down on the table and from \( t=65s \) to \( t=70s \), the robots diminish pushing. Figure 4 shows the simulation and experimental results of the joint coordinates, while Figure 5 shows the results in Cartesian coordinates. As can be appreciated, the results are good in both cases. On the other hand, the Figure 7 and 8 show only the experimental results, for demonstrate the accuracy of the controller-observer scheme. The Figure 7 show the observation error, as can be appreciated, they are pretty. Finally, Figure 8 show the input voltages. In can observed that there are not saturation problems. This demonstrates the efficacy of designing a decentralized controller.

6. Conclusions

In this chapter, we developed the model for two cooperative industrial robots holding a rigid object without friction. The dynamic model for the manipulators is obtained independently from each other with the Lagrangian approach. Once the robots are holding the object, their joint variables are kinematically and dynamically coupled. These coupling equations are combined with the dynamic model of the object to obtain a mathematical description for the cooperative system.

Besides, the tracking control problem for cooperative robots without velocity measurements is considered. The control law is a decentralized approach which takes into account motion constraints rather than the held object dynamics. By assuming that fingers dynamics are well known and that contact forces measurements are available, a linear observer for each finger is proposed which does not require any knowledge of the robots dynamics. Despite the fact that the stability analysis is complex, the controller and specially the observer are not.

Some experiments and simulations have been carried out to test the theoretical results. The overall outcome of the mathematical model compared with the real system can be considered good, which validates the approach used.
7. Appendix

A The A465 and A255 robot models.

This section presents the A465 and A255 robot models as well as the corresponding parameter values. The models used for implementation and simulation purposes include Coulomb friction term for both robots. The approach to model them can be found in any standard book for robotics (e.g. (Sciavicco & Siciliano 2000). Recall that only the first three degrees of freedom of each manipulator are being considered. Additionally, since the actuators are DC motors, their dynamics must be taken into account. Thus, for each manipulator (in free motion), one has
\[
H(q_i) \dot{q}_i + C_i(q_i, \dot{q}_i) \dot{q}_i + D_i \dot{q}_i + f_i(q_i) + g_i(q_i) = D^i_n D^i v_i,
\]
where \(f_i(q_i) \in \mathbb{R}^3\) represents the Coulomb friction term and \(D_n \in \mathbb{R}^{3 \times 3}\) are to be defined later. The motors inertias are included in the matrix \(H_i(q_i)\) so as to have a minimum set of parameters. The elements of matrices \(H_i(q_i), C_i(q_i, \dot{q}_i), f_i(q_i), g_i(q_i)\) of the model for Robot Arm A465 of CRS Robotics are computed as

&c_1(3,1) = q_{23} s_{13} p_{13} \\
&c_1(3,2) = -q_{23} \sin(q_{22} - q_{23})p_{13} \\
&c_1(3,3) = 0 \\
&f_{1\alpha}(1) = \frac{p_{13} \operatorname{sgn}(\dot{q}_{23})}{1} \\
&f_{1\alpha}(2) = \frac{p_{13} \operatorname{sgn}(\dot{q}_{23})}{1} \\
&f_{1\alpha}(3) = \frac{p_{13} \operatorname{sgn}(\dot{q}_{23})}{1} \\
&g_1(1) = 0 \\
&g_1(2) = c_1 p_{13} \\
&g_1(3) = c_1 p_{14} \\
&v_2^i = \{ v_{i1} \quad v_{i2} \quad v_{i3} \}. \quad \text{The motor dynamics data are } D_{\beta i} = \text{bloc diag} \left[ \frac{1}{t_{\alpha1}} \quad \frac{1}{t_{\alpha2}} \quad \frac{1}{t_{\alpha3}} \right] \text{ and}
\[ D = \text{bloc diag} \begin{bmatrix} k_{s1} & k_{s2} & k_{s3} \\ k_{m1} & k_{m2} & k_{m3} \\ k_{a1} & k_{a2} & k_{a3} \end{bmatrix} \]. With \( r_{21} = r_{22} = r_{23} = 72 \), \( K_{a21} = K_{a22} = K_{a23} = 0.0657 \text{ Nm/A} \) and \( R_{a21} = R_{a22} = R_{a23} = 2.40\). Note that in the model of both robots we could have chosen the parameters in a different fashion to have a smaller set. However, we made the definitions according to the computation of the inertia of the links. The elements of the analytical Jacobian \( J(\mathbf{q}) \) of robot A465 are given by

\[
J_{13}(\mathbf{q}) = \begin{bmatrix}
-a_{2} s_{2} c_{2} - (d_{3} + d_{4}) s_{4} \sin(q_{12} + q_{13}) \\
-a_{2} c_{2} s_{2} + (d_{3} + d_{4}) c_{4} \cos(q_{12} + q_{13}) \\
(d_{3} + d_{4}) c_{4} \cos(q_{12} + q_{13})
\end{bmatrix}
\]

and the constraint Jacobian matrix \( J_{\varphi}(\mathbf{q}) \) of the robot arm A465 is:

\[
J_{\varphi}(\mathbf{q}) = \begin{bmatrix}
-a_{2} s_{2} c_{2} - (d_{3} + d_{4}) s_{4} \sin(q_{12} + q_{13}) \\
-a_{2} c_{2} s_{2} + (d_{3} + d_{4}) c_{4} \cos(q_{12} + q_{13}) \\
(d_{3} + d_{4}) c_{4} \cos(q_{12} + q_{13})
\end{bmatrix}
\]

and the constraint Jacobian matrix \( J_{\varphi}(\mathbf{q}) \) of the robot arm A255 is:

\[
J_{\varphi}(\mathbf{q}) = \begin{bmatrix}
-a_{2} s_{2} c_{2} - a_{2} s_{3} c_{3} - d_{2} s_{4} \\
-a_{2} c_{2} s_{2} + a_{2} s_{3} c_{3} + d_{2} c_{4} \\
-a_{2} c_{2} s_{2} + a_{2} s_{3} c_{3} + d_{2} c_{4}
\end{bmatrix}
\]

Note that, for simplicity, both \( J_{\varphi}(\mathbf{q}) \) and \( J_{\varphi}(\mathbf{q}) \) are expressed with respect with an inertial system fixed at the base of robot A255.
$$p_1 = 0.0055 \text{ kg m}^2 \quad p_2 = 0.0080 \text{ kg m}^2 \quad p_3 = 0.0024 \text{ kg m}^2 \quad p_4 = 0.0118 \text{ kg m}^2 \quad p_5 = 0.0041 \text{ kg m}^2$$

**B Proof of Lemma 4.1**

In this appendix Lemma 4.1 is proven, whose main assumption is that \(\begin{bmatrix} s' \, r' \, \Delta F' \, \phi' \end{bmatrix}\) is bounded by \(X_{\text{max}}\) and tends to zero.

a) First of all we show that \(\Delta p_i\) and \(\Delta \dot{p}_i\) are bounded for all time, with \(i = 1, \ldots , l\). To do this we use the fact that \(J_i'(q_i)s_i = \Delta p_i + \beta \Delta p_i - \frac{\partial}{\partial q_i} \dot{\phi} - \ddot{\phi}\Delta F\) or

\[
\Delta \dot{p}_i + \beta \Delta p_i = J_i'(q_i)s_i + \frac{\partial}{\partial q_i} \dot{\phi} + \ddot{\phi}\Delta F.
\]  

(99)

The righthand side of equation (99) is bounded and tends to zero because of the assumption on \(x_i\). Since the lefthand side of (99) represents a stable linear filter, both \(\Delta p_i\) and \(\Delta \dot{p}_i\) must be bounded and tend to zero.

b) The next step is to analyze the behavior of the tracking errors \(\dot{q}_i\) and \(\ddot{q}_i\). Since \(x_i\) is bounded, so is \(s_i\). According to (41), both \(s_{pi}\) and \(s_{fi}\) are bounded since they are orthogonal vectors. Note that \(s_{pi}\) can be written as

\[
s_{pi} = Q(q_i)(\dot{q}_i + A\dot{q}_i - Az_i) - (I - J_i^n J_i^n)(\dot{q}_i + A\dot{q}_i - Az_i),
\]  

(100)

in view of the definition of \(Q(q_i)\). Equation (100) can be rewritten as

\[
\dot{q}_i + A\dot{q}_i = Az_i + Q(q_i)(\dot{q}_i + A\dot{q}_i - Az_i) - I J_i^n J_i^n Az_i + I J_i^n (\dot{q}_i + A\dot{q}_i).
\]  

(101)

One can be sure that the first terms in (101) are bounded because the case is being analyzed when \(x_i\) in (63) is bounded. The conclusion can be drawn from equations (13)-(14) (boundedness of \(J_i^n\) and \(J_i^n\)), equations (51) and (63) (boundedness of \(z_i\)), and equation (100) (boundedness of \(Q(q_i)(\dot{q}_i + A\dot{q}_i - Az_i)\)). It is then clear that if the last term of the righthand side of (101) is bounded, then \(\ddot{q}_i\) and \(\dot{q}_i\) must be bounded since the lefthand side of (101) represents a stable linear filter. Note then that

\[
I J_i \dot{q}_i = \dot{p}_i - p_{id} - (J_i^n J_i^n) \ddot{q}_i
\]  

(102)

is bounded, with \(I J_i = J_i(q_i)\). Thus, the lefthand side of (101) can only be unbounded if

\[
I J_i A \ddot{q}_i = I J_i A (\dot{q}_i - q_{id})
\]  

is not bounded. But in fact this term will be bounded as long as \(q_i\) is. At this point we recall that, from Assumption 3.1, \(q_i\) must satisfy the constraint \(\phi(q_i) = 0\). Furthermore, it has been assumed that none of the robots is redundant nor it is in a singularity. Thus, the

\[1\] Note that we do this only for formality's sake, since these two errors are bounded and equal to zero for any time in view of the fact that all \(p_i\), \(p_{id}\), \(p_i\), and \(p_{id}\) are.
constraint can only be satisfied by a finite bounded vector \( q \). We can then conclude, that both \( \dot{q}_i \) and \( \ddot{q}_i \) remain bounded as long as \( x_i \) is. To show that the tracking errors tend to zero whenever \( x_i \) does, we use the following approach. If \( x_i = 0 \) then \( s \) becomes

\[
Q_i(q_i)(\ddot{q}_i + A_i \dot{q}_i) + J_{w_i}(q_i)(J_{w_i}(q_i)\dot{q}_i - J_{w_i}(q_{\text{a}})\dot{q}_{\text{a}}) + \beta_i(q_i - \phi(q_i)) = 0.
\]  

(103)

Suppose that \( q_i = q_{\text{a}} \), then (103) becomes

\[
Q_i(q_i)\ddot{q}_i + J_{w_i}(q_i)J_{w_i}(q_i)\dot{q}_i = \dot{\dot{q}}_i = 0.
\]  

(104)

This shows that if \( \|\dot{q}_i\| \to 0 \) then \( \|\ddot{q}_i\| \to 0 \). In other words, by proving that \( \ddot{q}_i \) will tend to zero one can ensure that \( \dot{q}_i \) will do it as well. Since homogeneous constraints are being used, the following relationship is satisfied

\[
\Delta p = \phi(q_i) - \phi(q_{\text{a}}).
\]  

By developing a Taylor series around the desired trajectory \( q_{\text{a}} \) we have for \( \phi(q_i) \)

\[
\phi(q_i) = \phi(q_{\text{a}}) + \frac{\partial \phi}{\partial q} \bigg|_{q_{\text{a}}} (q_i - q_{\text{a}}) + \text{h.o.t.}
\]  

(105)

There exists a positive value \( \eta_i \) small enough such that if

\[
\|q_i\| \leq \eta_i,
\]  

then the higher order terms in (105) can be neglected and the approximation

\[
\Delta p = J_{w_i}(q_i)\ddot{q}_i,
\]  

(107)

becomes valid. The following discussion will be carried out assuming that (106) is holding. To prove that \( \ddot{q}_i \) tends to zero we require to find a dynamic equation which describes the behavior of this variable. It can be formed in the following fashion. From \( s_{\text{p}} \), in (41) one gets

\[
\ddot{q}_i s_{\text{p}} = \dddot{q}_i A_i \dot{q}_i + \dddot{q}_i A_i \dot{q}_i - \dddot{q}_i A_i z_i - \dddot{q}_i P_i \dot{q}_i - \dddot{q}_i P_i A_i \dot{q}_i + \dddot{q}_i P_i A_i z_i,
\]  

(108)

with \( \dddot{q}_i \Gamma_i(q_i) \Gamma_{\text{a}}(q_i) \). In view of the fact that

\[
\dddot{q}_i \dot{q}_i = \|\dot{q}_i\|^2 \frac{d}{dt}\|\dot{q}_i\|,
\]

one can rewrite (108) as

\[
\|\dot{q}_i\|^2 \frac{d}{dt}\|\dot{q}_i\| = -\dddot{q}_i A_i \dot{q}_i + \dddot{q}_i P_i \dot{q}_i + \dddot{q}_i P_i A_i \dot{q}_i + \dddot{q}_i P_i A_i z_i - \dddot{q}_i P_i A_i z_i - \dddot{q}_i P_i A_i z_i + \dddot{q}_i P_i A_i z_i + \dddot{q}_i s_{\text{p}}.
\]  

(109)

To develop the righthand side of this equation we analyze the term \( q_i \Gamma_i \Gamma_{\text{a}} \) first. From (102)

\[
\Delta p = J_{w_i}(q_i + (J_{w_i} - J_{\text{a}})q_{\text{a}}.
\]  

(110)

By multiplying (107) by \( \beta_i \) and adding the result to (110) one gets

\[
J_{w_i}(q_i + \beta_i J_{w_i} q_{\text{a}}) = \Delta p_i + (J_{w_i} - J_{\text{a}})q_{\text{a}} + \beta_i \Delta p_i.
\]  

(111)

Thus we have
\[ \bar{q}^T \bar{P} \dot{q} = \bar{q}^T J^T (J \omega - \omega_d) \dot{q} \]
\[ = -\beta \bar{q}^T \bar{P} \dot{q} + \bar{q}^T J^T \Delta \dot{p} + \bar{q}^T J^T \Delta \dot{p} - \dot{q}^T J^T (J \omega - \omega_d - \beta \dot{q}). \] (112)

Substituting in (109) one gets
\[ \| \dot{q} \| \frac{d}{dt} \| \dot{q} \| = -k_1 \| \dot{q} \|^2 + (k_1 - \beta_1) \bar{q}^T \bar{P} \dot{q} - \bar{q}^T J^T (J \omega - \omega_d - \beta \dot{q}) \]
\[ + \bar{q}^T J^T \Delta \dot{p} + \bar{q}^T J^T \Delta \dot{p} + k_1 \bar{q}^T \bar{Q} z + \bar{q}^T \bar{x}_m, \] (113)

where the definition \( \bar{A} \triangleq k_1 I \) has been used. In view of Assumption 3.2, the following bound can be established
\[ \| \bar{q}^T J^T (J \omega - \omega_d)(\hat{q}_d - \beta \dot{q}) \| \leq \gamma \| \dot{q} \|^2, \] (114)
with
\[ \gamma = c_0 k \| \bar{Q} \| + \beta_1 . \] (115)
\( \bar{V}_{m1} \) is a bound for the desired velocity vector \( \bar{d}_d \), i.e. \( \| \bar{d}_d \| \leq \bar{V}_{m1} \) for all time, and \( c_0 \) and \( L_i \) are defined in (13)-(14). On the other hand, from (41) you have
\[ s_w = s - f_s(\zeta) \left( \alpha \bar{p} + \beta_1 \Delta \bar{p} - \bar{E} \bar{x} - \xi \Delta \bar{F} \right). \] (116)

By substituting (114)-(116) in (113), taking norms and dividing by \( \| \dot{q} \| \) one gets
\[ \frac{d}{dt} \| \dot{q} \| \leq -\alpha_1 \| \dot{q} \| + k_1 \| s \| + \lambda \| \bar{Q} \| + \bar{\lambda} \bar{x}_m(\xi) \| \bar{Q} \| + \bar{\lambda} \bar{x}_m(\xi) \| \Delta \bar{F} \| + k_1 \| \bar{x} \|, \] (117)
with
\[ \alpha_1 \triangleq k_1 \| \bar{Q} \| + \beta_1 - \gamma_1. \]

Note that \( k_1, \beta_1, \bar{V}_{m1} \) and \( \eta_1 \) can always be chosen so as to get \( \alpha_1 > 0 \) and that the last four elements of the right hand side of (117) are bounded since \( s \) is. However, (117) is valid only if (106) holds. Thus, in the end, it is not enough for \( \bar{x} \) to be bounded. We must find a bound \( x_{\text{max}} \) such that (106) holds. In order to guarantee this, \( x_{\text{max}} \) should appear in (117) explicitly. Of course, if \( \| \bar{x} \| \leq x_{\text{max}} \), then one has
\[ \| \bar{x} \| = \| \bar{s} \| + \| \bar{Q} \| + \| \Delta \bar{F} \| \leq x_{\text{max}}, \] (119)
with \( r = \bar{s} + \bar{A}_i \bar{z}_i \). Since in (117) one has \( \bar{z}_i \) and not \( r_i \), it should be noted that every element of \( \bar{z} \) is given by \( r_{ij} = \bar{s}_{ij} + k_i \bar{z}_{ij} \), for \( j = 1, \ldots, n_i \). This is a stable linear filter with gain \( \frac{1}{k_i} \), i.e. one has \( \| \bar{z}_i \| \leq \frac{\| \bar{s}_{ij} \|}{k_i} \). Thus, it is straightforward to show that
\[ \| \bar{z} \| \leq \frac{\| \bar{r} \|}{k_i} x_{\text{max}}, \] (120)
which allows to rewrite (117) as
\[ \frac{d}{dt} \| \dot{q} \| \leq -\alpha_1 \| \dot{q} \| + \sigma, \] (121)
with
\[ \sigma \triangleq (1 + \bar{\lambda} \bar{x}_m(\xi)) \| \bar{Q} \| + \bar{\lambda} \bar{x}_m(\xi) \| \Delta \bar{F} \| + \bar{\lambda} \bar{x}_m(\xi) \| \bar{Q} \| \| \bar{Q} \| \| \Delta \bar{F} \| x_{\text{max}}, \] (122)
From the Comparison Lemma (Khalil 2002), it is
\[ v(t) \leq \frac{\sigma_t}{\alpha_t} + e^{-w_t} \left( \left\| v(0) \right\| - \frac{\sigma_t}{\alpha_t} \right) \]  \tag{123}

for all time. Equation (106) will be satisfied for sure if

\[ \left\| v(0) \right\| \leq \frac{\sigma_t}{\alpha_t} \left( 1 + \lambda_{\text{max}} \left( \xi \right) c_{\alpha} + \lambda_{\text{max}} \left( \xi \right) c_{\alpha} + \sqrt{\eta} \right) x_{\text{max}} \leq \eta, \]  \tag{124}

Equation (124) can be accomplished if

\[ x_{\text{max}} \leq \frac{\eta \alpha_t}{1 + \lambda_{\text{max}} \left( \xi \right) c_{\alpha} + \lambda_{\text{max}} \left( \xi \right) c_{\alpha} + \sqrt{\eta}}. \]  \tag{125}

Finally, if \( \left\| x \right\| \) tends to zero, it is clear from (117) that \( \left\| \dot{\theta} \right\| \) will do it as well. Recall that this implies the convergence to zero of \( \dot{\theta} \).

c) When \( X_i \) (and thus \( \Delta F_i \)) tend to zero, \( \Delta \lambda_i \) does not necessarily do it nor remains bounded. In order to prove that, one may use the fact that

\[ J_i (q_i) s_i = \Delta p_i + \beta \Delta p_i - \xi_i \Delta \lambda_i - \xi_i \Delta F_i = -\xi_i A \phi - \xi_i B \Delta \lambda_i - \xi_i \Delta F_i. \]  \tag{126}

or

\[ \Delta \lambda_i = \left( \xi_i B_i + \xi_i \right) \text{det} \left( J_i (q_i) s_i + J_i (q_i) s_i \right), \]  \tag{127}

Where (45) has been used. Since from (57) \( \dot{S_i} \) is bounded when \( X_i \) is, we conclude that \( \Delta \lambda_i \) must be bounded (recall the assumption on \( \dot{\theta} \)). Finally, if \( X_i \) tends to zero then \( \dot{S_i}, s_i \) and \( \phi \) do and we arrive to the conclusion that \( \Delta \lambda_i \) tends to zero as well.

C Positive definiteness of \( V_i (x_i) \) in (65)

To prove that \( V_i (x_i) = \frac{1}{2} x_i^T \text{block diag} \{ H_i (q_i), H_i (q_i), R_i \} x_i \) in (65) is actually a positive definite function, recall first that such a function must satisfy that \( V_i (0) = 0 \) and \( V_i (x_i) > 0 \) for \( x_i \neq 0 \). Since \( H_i (q_i) \) is a positive definite matrix, the single problem is that \( R_i \) in (66) is only semipositive definite. However, developing the term in (65) which involves \( R_i \) yields

\[ \frac{1}{2} \dot{\phi}^T \Delta F_i^T R_{\Delta F_i} \dot{\phi} = \frac{1}{2} \left( B_i^2 \phi - B_i^2 \Delta F_i \right)^T N_i \left( B_i^2 \phi - B_i^2 \Delta F_i \right), \]  \tag{128}

since \( B_i \) is a positive definite diagonal matrix. In view of the fact that \( N_i > 0 \), (128) can only be zero if

\[ \phi = B_i \Delta F_i. \]  \tag{129}

On the other hand, note that \( V_i (x_i) \) includes a term \( \frac{1}{2} s_i^T H_i (q_i) s_i \) which can be zero only if \( s_i = 0 \). Otherwise, it is positive. But from (41) you have \( s_i = s_{p_i} + s_{f_i} \), where \( s_{p_i} \) and \( s_{f_i} \) are
orthogonal, so that they both must be zero in order for \( S_i \) to be zero. In particular, one has
\[ s_i = J_{i*}(q_i)\left(\Delta \dot{q}_i + \beta_i \Delta q_i - \frac{\xi_i}{\xi_i} \Delta F_i\right), \]
with \( J_{i*}(q_i) \) full rank. Then, in view of constraint (6), you have that \( S_i \) becomes zero only if \( \frac{\xi_i}{\xi_i} + \frac{\Delta F_i}{\xi_i} \) does, that is if
\[ \phi = -\frac{\xi_i}{\xi_i} \Delta F_i. \] (130)

Comparing (129) with (130) one concludes that
\[ \frac{1}{2} s_i^T H_i(q_i) s_i \] and (128) cannot be simultaneously zero unless both \( \phi \) and \( \Delta F_i \) are, because \( B_i, \xi_i \) and \( \xi_i \) are all positive definite diagonal matrices. In other words, \( V_i(x_i) \equiv 0 \) if and only if \( x_i = 0 \). Thus, it is a (continuous) positive definite function.

**D Proof of Theorem 4.1**
Recall the following well known theorem (Khalil 2002, pp. 100)

**Theorem D.1** Let \( x = 0 \) be an equilibrium point for \( \dot{x} = f(x) \) and \( \mathbb{D} \subset \mathbb{R}^n \) be a domain containing \( x = 0 \). Let \( V : \mathbb{D} \rightarrow \mathbb{R}^n \) be a continuously differentiable function, such that \( V(0) = 0 \) and \( V(x) > 0 \) in \( \mathbb{D} - \{0\} \), and \( \dot{V}(x) \leq 0 \) in \( \mathbb{D} \). Then, \( x = 0 \) is stable. Moreover, if \( \dot{V}(x) < 0 \) in \( \mathbb{D} - \{0\} \) then \( x = 0 \) is asymptotically stable.

To take advantage of Theorem D.1, we just have to find domains \( \mathbb{D}_i \) for which each \( V_i(x_i) \) satisfies \( \dot{V}_i(x) < 0 \) in \( \mathbb{D}_i - \{0\} \) (because each \( V_i(x_i) \) is positive definite in \( \mathbb{R}^n \)). In doing so, one can prove that \( x_i \rightarrow 0 \) for all \( i \). Then, Lemma 4.1 can be employed to analyze the behavior of the different error signals. Based on the discussion given in Appendix B, we define each domain \( \mathbb{D}_i \) as
\[ \mathbb{D}_i = \left\{ x_i \in \mathbb{R}^n \mid \|x_i\| \leq x_{\text{max}} \right\}, \] (131)
where \( x_{\text{max}} \) is chosen to satisfy (125) and cannot be done arbitrarily large. In \( \mathbb{D}_i \) one can define
\[ \mu_i = \max_{[q_i, q_i]} \|C_i(q_i, \dot{q}_i)\| \] (132)
\[ \mu_{ii} = \max_{[\dot{q}_i, \dot{q}_i]} \|C_i(q_i, \dot{q}_i)\| \] (133)
\[ \mu_{i\dot{q}_i} = \max_{[q_i, q_i]} \|C_i(q_i, \dot{q}_i)\| \] (134)
\[ \mu_{\dot{q}_i} = \max_{[\dot{q}_i, \dot{q}_i]} \|C_i(q_i, \dot{q}_i)\| \] (135)
\[ \lambda_{\text{max}}(D_i) \] (136)

Note that it is straightforward to compute (132)-(136) as functions of the different constants defined throughout the paper, but we skip it for simplicity’s sake. The next step is to compute the derivative of the Lyapunov function candidate in (65), which can be rewritten as
\[ V_i(x_i) = \frac{1}{2} s_i^T H_i(q_i) s_i + \frac{1}{2} r_i^T H_i(q_i) r_i + \frac{1}{2} \phi^T \Delta F_i \]
Then, the derivative of (65) along (42), (45), (57) and (62) can be computed as
\begin{equation}
\dot{V}(x_i) = \frac{1}{2} s_i^T H_i(q_i) s_i + \frac{1}{2} r_i^T H_i(q_i) r_i - s_i^T C_i(q_i, q_i) s_i - s_i^T K_{\text{def}, s_i} + s_i^T K_{r_i, s_i}^T (q_i) (B_i^A A_i \phi + K_{\phi_i} \Delta F_i) - s_i^T C_i(q_i, q_i) s_i + s_i^T J_i^T(q_i) (B_i^A A_i \phi + K_{\phi_i} \Delta F_i)
\end{equation}

To simplify (137) one should take into account that $s_i^T K_{r_i, s_i}^T (q_i) (B_i^A A_i \phi + K_{\phi_i} \Delta F_i) = -s_i^T F_i \xi K_{r_i}^T \Delta F_i - s_i^T D_i r_i$. The last equality is valid in view of Property 3.5, from (41) and by the fact that constraint (6) must be satisfied for $p_i, p_{i_d}$ and $p_{i_d}$. Furthermore, one has

\begin{equation}
\left[ \dot{\xi}^T \Delta F_i^T \right] \begin{bmatrix} N_i B_i^T \hline -N_i \end{bmatrix} \begin{bmatrix} \xi_i \\ \Delta A_i \end{bmatrix} = -d_i^T N_i B_i^T A_i \phi + \Delta F_i N_i A_i \phi
\end{equation}

in view of (45). Recalling that $N_i = (\xi B_i^A A_i + \xi K_{r_i}) A_i^T$ and defining $E_i \in (\xi B_i^A A_i + \xi K_{r_i}) A_i^T$, (137) can be simplified to

\begin{equation}
\dot{V}(x_i) \leq \frac{1}{2} -s_i^T K_{r_i, s_i} + s_i^T J_i^T(q_i) (B_i^A A_i \phi + r_i J_i^T(q_i) K_{\phi_i} \Delta F_i - s_i^T D_i r_i + s_i^T H_i(q_i) e(r_i) - r_i C_i(q_i, q_i, s_i) + r_i J_i^T(q_i) B_i^A A_i \phi + r_i J_i^T(q_i) K_{\phi_i} \Delta F_i - s_i^T C_i(q_i, q_i, s_i) + r_i C_i(q_i, q_i, s_i) + r_i J_i^T(q_i) K_{\phi_i} \Delta F_i - s_i^T C_i(q_i, q_i, s_i) + r_i C_i(q_i, q_i, s_i) + r_i J_i^T(q_i) K_{\phi_i} \Delta F_i
\end{equation}

by taking Property 3.2 into account. Since we are only interested in the behavior of $\dot{V}(x_i)$ for $X_i$ in $D_i$, we have from (132)-(136)

\begin{equation}
\dot{V}(x_i) \leq -\lambda_{\text{min}}(K_{\phi_i}) \| \xi_i \| - \lambda_{\text{min}}(H_{\phi_i}) \| \xi_i \| + \lambda_{\text{min}}(E_i) \| \dot{\xi}_i \| - \lambda_{\text{min}}(\xi K_{r_i}) \| \Delta F_i \|
\end{equation}

where $c_i$ is given in (14) and

\begin{equation}
b_i \equiv \max \{ b_i^j \}
\end{equation}

\begin{equation}
a_i \equiv \max \{ a_i^j \}
\end{equation}

$a_i$ and $b_i$ with $j = 1, \ldots, n_i$, are elements of $A_i$ and $B_i$, respectively. The next step is to choose the different gains to guarantee that $\dot{V}(x_i) < 0$ in $D_i - 0$. First of all, consider $\lambda_{\text{min}}(K_{\phi_i})$ in (70) and $k_{d_i}$ in (71), such that one has from the first line of (139)\n
\begin{equation}
- (\mu_{i_1} + 1 + \delta_i) \| \dot{\xi}_i \| \leq \mu_{i_1} \| \dot{\xi}_i \| + (\lambda_{\text{min}}(K_{\phi_i}) + w_1) \| \xi_i \| - \lambda_{\text{min}}(K_{\phi_i}) \| \xi_i \| \leq -\delta_i \| \xi_i \| - \delta_i \| \xi_i \| - \frac{1}{4} c_i^2 \| \xi_i \| + \frac{1}{4} c_i^2 \lambda_{\text{min}}(K_{\phi_i}) \| \xi_i \| \| \Delta F_i \|,
\end{equation}

because $w_i = \mu_{i_1} + 1 + \delta_i \| \dot{\xi}_i \|$, $\lambda_{\text{min}}(K_{\phi_i}) + w_1$, $\lambda_{\text{min}}(K_{\phi_i})$, $\lambda_{\text{min}}(K_{\phi_i})$, and $\lambda_{\text{min}}(K_{\phi_i})$. Thus, (139) becomes
\[
V_i(x_i) \leq -\delta \|s_i\|^2 - \delta \|r_i\|^2 - \left(\frac{1}{4} c_i^2 a_i^2 h_i^2 + \frac{1}{4} c_i^2 \lambda_{\max}^2(K_{ri})\right) \|r_i\|^2 \\
- \lambda_{\max}(\xi_i) \|\xi_i\|^2 - \lambda_{\min}(\xi_i) \|\Delta F_i\|^2 \\
+ c_i a_i h_i \|\xi_i\| \|\xi_i\| + c_i \lambda_{\max}(K_{ri}) \|\Delta F_i\|.
\]

(142)

Finally, by considering \(\lambda_{\max}(\xi_i)\) in (72) and \(\lambda_{\min}(\xi_i)\) in (73) it is easy to conclude that

\[
V_i(x_i) \leq -\delta \|s_i\|^2 - \delta \|r_i\|^2 - \delta \|\xi_i\|^2 - \delta \|\Delta F_i\|^2
\]

(143)
or

\[
\dot{V}_i(x_i) \leq -\delta \|s_i\|^2 - \delta \|r_i\|^2.
\]

(144)

By applying Theorem D.1 one concludes that \(x_i \rightarrow 0\). Now, from definition (51) one has directly

\[
\lim_{t \to \infty} z_i = 0 \quad \lim_{t \to \infty} \dot{z}_i = 0.
\]

Furthermore, in view of (131) one has \(\|x_i\| \leq x_{\max}\) (and thus \(\|\tilde{q}_i\| \leq \eta_i\) from the discussion in Appendix B). Thus, from Lemma 4.1 a) and b), we get

\[
\lim_{t \to \infty} \Delta \tilde{p}_i = 0 \quad \lim_{t \to \infty} \Delta \tilde{q}_i = 0
\]

To applied c) of Lemma 4.1, we only need to show that \(\tilde{q}_i\) is bounded. This is certainly the case because \(\tilde{q}_i\) and \(\tilde{q}_{\text{tot}}\) are bounded. Thus we get

\[
\lim_{t \to \infty} \Delta \tilde{q}_i = 0.
\]

Finally, the stability of the whole system can be proven using

\[
V = \sum_{i=1}^{n} V_i(x_i).
\]

It should be noted that a region of attraction has not been given explicitly. However, it is a subset of \(D_i\) and cannot be made arbitrarily large because of the fact that \(\|x_i\| \leq \eta_i\) must hold for all time (and thus \(\|\tilde{x}_i\| \leq x_{\max}\) must be valid as well), with \(\eta_i\) small enough.

7. References

This book covers many aspects of the exciting research in mobile robotics. It deals with different aspects of the control problem, especially also under uncertainty and faults. Mechanical design issues are discussed along with new sensor and actuator concepts. Games like soccer are a good example which comprise many of the aforementioned challenges in a single comprehensive and in the same time entertaining framework. Thus, the book comprises contributions dealing with aspects of the Robotcup competition. The reader will get a feel how the problems cover virtually all engineering disciplines ranging from theoretical research to very application specific work. In addition interesting problems for physics and mathematics arises out of such research. We hope this book will be an inspiring source of knowledge and ideas, stimulating further research in this exciting field. The promises and possible benefits of such efforts are manifold, they range from new transportation systems, intelligent cars to flexible assistants in factories and construction sites, over service robot which assist and support us in daily live, all the way to the possibility for efficient help for impaired and advances in prosthetics.
